Molecular, Immunological, and Structural Characterization of Phl p 6, a Major Allergen and P-Particle-Associated Protein from Timothy Grass (Phleum pratense) Pollen

Susanne Vrtala, Sabine Fischer, Monika Grote, Luca Vangelista, Annalisa Pastore, Wolfgang R. Sperr, Peter Valent, Rudolf Reichelt, Dietrich Kraft, and Rudolf Valetta

Due to the wide distribution and heavy pollen production of grasses, ~50% of allergic patients are sensitized against grass pollen allergens. cDNAs coding for two isoforms and four fragments of a major timothy grass (Phleum pratense) pollen allergen, Phl p 6, were isolated by IgE immunoscreening from a pollen expression cDNA library. Recombinant Phl p 6 (rPhl p 6), an acidic protein of 11.8 kDa, was purified to homogeneity as assessed by mass spectrometry and exhibited almost exclusive α-helical secondary structure as determined by circular dichroism spectroscopy. Phl p 6 reacted with serum IgE from 75% of grass pollen-allergic patients (n = 171). IgE binding experiments with rPhl p 6 fragments indicated that the N terminus of the allergen is required for IgE recognition. Purified rPhl p 6 elicited dose-dependent basophil histamine release and immediate type skin reactions in patients allergic to grass pollen. A rabbit antiserum raised against purified rPhl p 6 identified it as a pollen-specific protein that, by immunogold electron microscopy, was localized on the polysaccharide-containing wall-precursor bodies (P-particles). The association of Phl p 6 with P-particles may facilitate its intrusion into the deeper airways and thus be responsible for the high prevalence of IgE recognition of Phl p 6. Recombinant native-like Phl p 6 can be used for in vitro as well as in vivo diagnoses of grass pollen allergy, whereas N-terminal deletion mutants with reduced IgE binding capacity may represent candidates for immunotherapy of grass pollen allergy with a low risk of anaphylactic side effects. The Journal of Immunology, 1999, 163: 5489–5496.

Type I allergy is a genetically determined hypersensitivity disease that affects >20% of the population in industrialized countries (1). As a consequence of this immunodisorder, allergic patients produce IgE Abs against per se innocuous, mostly airborne proteins from pollen, mites, moulds, and animal hair/dander. The symptoms of type I allergy (allergic rhinitis, conjunctivitis, allergic asthma, and anaphylactic shock) result from allergen-induced cross-linking of effector cell (mast cell, basophil)-bound IgE Abs and subsequent release of inflammatory mediators (2). Because ~40% of allergic individuals suffer symptoms after contact with grass pollen, research has concentrated on the characterization of relevant grass pollen allergens by protein and immunochemical methods (3). Although groups of major allergens have been identified as cross-reactive moieties that occur in most grass species (4), nothing was known concerning their nature and biological functions.

Phl p 6 predominantly on the polysaccharide-containing wall-precursor bodies (P-particles) of mature timothy grass pollen. This unique feature may possibly indicate that the high rate of sensitization of patients allergic to grass pollen against Phl p 6 is due to P-particle-linked intrusion of Phl p 6 into the deeper airways. The greatly reduced IgE binding capacity of N-terminally truncated rPhl p 6 indicates that N-terminal deletion variants of Phl p 6 may be considered as hypoallergenic candidate molecules for immunotherapy of grass pollen allergy.

Materials and Methods

Biological materials, patients’ sera, antiserum, and recombinant allergens

Pollen from timothy grass (Phleum pratense), rye grass (Lolium perenne), rye (Secale cereale), Kentucky blue grass (Poa pratensis), wheat (Triticum sativum), cultivated oat (Avena sativa), and common reed (Phragmites communis) were from Allergon (Växjö, Sweden). Timothy grass seeds were purchased from Austrosaat (Vienna, Austria) and grown for 4 wk to obtain fresh leaves and roots. Patients allergic to grass pollen were characterized as described previously (4). The rabbit anti-celery profilin antiserum was raised against purified rPhl p 6 using CFA (Charles River, Germany). The recombinant timothy grass pollen allergens rPhl p 1, rPhl p 2, and rPhl p 5 were purified as described previously (13). Recombinant timothy grass pollen profilin was purified by poly(L-proline) affinity chromatography (6).

Isolation and characterization of cDNAs coding for Phl p 6 isoforms/fragments

A total of 350 IgE-reactive clones were isolated from an expression cDNA library constructed from mature timothy grass pollen in phage Agt 11 (14). Six cDNAs (c121, c142, c146, c171, c223, and c233) with sequence homology to a Phl p 6-encoding cDNA (15) were subcloned into plasmid pUC18 and sequenced (16, 17). Sequences were analyzed using the McVector program (Kodak, Rochester, NY). A search for Phl p 6-homologous protein sequences was done with the FastA program (GCG package) (18) in the SwissProt database. The sequences of Hol 1 5 and Hor v 5 allergens were retrieved from the European Molecular Biology Laboratory (EMBL) database. A multiple sequence alignment was produced with ClustalW (19) and edited by hand. The GDE sequence editor (S. Smith, Harvard University, Cambridge, MA) and Colormask (J. Thompson, EMBL, Heidelberg, Germany) were used to color conserved residues with related properties (19). Protein secondary structure and surface accessibility predictions were done with the PHD program on the EMBL Predict-Protein server (20).

Mapping of Phl p 6 IgE epitopes, expression, and purification of rPhl p 6

The IgE binding capacity of phage clones expressing Phl p 6 isoforms and fragments was investigated by a plaque lift assay (21). The DNA coding for the mature Phl p 6 allergen was PCR-amplified from the clone 142 DNA and subcloned into the NdeI/EcoRI site of pET-17b. rPhl p 6 was expressed in E. coli BL21 (DE3) in liquid culture. Cells were suspended in 25 mM imidazole (pH 7.4) and 0.1% Triton X-100 and lysed by the addition of lysozyme (20 μg/ml) for 30 min at room temperature as well as by freeze-thawing cycles. DNA was digested with DNase I (0.1 mg/ml cell pellet) for 20 min at room temperature. The protein extract was centrifuged for 20 min at 10,000 g (Sorvall, Wilmington, DE) RC5C, SS34 rotor) to remove insoluble materials. rPhl p 6 was enriched in a precipitate obtained by the addition of ammonium sulfate (40–60% w/v). The precipitate was dissolved in 10 mM Tris (pH 6) and dialyzed against this buffer; after centrifugation (20 min at 10,000 g, Sorvall RC5C, SS34 rotor), the precipitate was applied to a DEAE-cellulose-Sepharose column (Pharmacia). Unbound proteins were eluted with 10 mM Tris (pH 6) and 4% v/v isopropanol. Fractions containing >80% pure Phl p 6 were adjusted to a pH of 8 with NaOH and subjected to a second chromatography step on a DEAE-cellulose-Sepharose column. Elution of bound proteins with a 0–0.5 M NaCl gradient at a pH of 8 yielded fractions containing pure rPhl p 6; these fractions were dialyzed against double distilled H2O.

Matrix-assisted laser desorption and ionization (MALDI)-time of flight (TOF) and CD analysis of purified rPhl p 6

Laser desorption mass spectra were acquired in a linear mode with a TOF Compact MALDI II instrument (Kratos, Manchester, U.K.) (pChem, Graz, Austria). CD spectra were recorded on a Jasco (Tokyo, Japan) J-710 spectropolarimeter fitted with a Jasco FT-348WI Peltier type temperature control system and interfaced with a Paramax N.I. GH water bath. Far-UV CD spectra were recorded at 20°C in a 2-mm path-length quartz cuvette (Hellma, Mullheim, Baden, Germany) at a protein concentration of 7 μM. Thermal denaturation of Phl p 6 was monitored by recording the ellipticity during temperature increase (50°C/1°C) at 220 nm. The reversibility of the unfolding process was checked by measuring the restoration of the CD signal upon cooling (50°C/1°C) to the starting temperature (20°C). The fraction of folded protein was calculated as

\[
\text{F} = \frac{\text{U} - \text{U}_0}{\text{U}_0 - \text{U}_\text{eq}}
\]

where \(\text{U}_0\) is the ellipticity at the native state and \(\text{U}_\text{eq}\) is the ellipticity of the protein in the denatured state. For rPhl p 6, \(\text{U}_0\) was assumed to be equal to \(\text{U}_{220}\) at 85°C and \(\text{U}_\text{eq}\) was assumed to be equal to \(\text{U}_{220}\) at 20°C.

IgE-binding capacity of rPhl p 6, and cross-reactivity with natural Phl p 6 and other timothy grass pollen allergens

The prevalence of IgE anti-rPhl p 6 reactivity was determined in sera from 171 patients allergic to grass pollen and, for control purposes, in sera from nonatopic persons by ELISA (13). The presence of cross-reactive IgE epitopes on natural Phl p 6 and rPhl p 6 was investigated by IgE immuno- blot inhibition experiments (4). A possible immunological relationship between rPhl p 6 and recombinant timothy grass pollen allergens (rPhl p 1, rPhl p 2, rPhl p 5) (13) was studied by ELISA competition as described previously (4).

Histamine release experiments

Granulocytes were isolated from heparinized blood samples of individuals allergic to grass pollen; the samples contained rPhl p 6-reactive IgE Abs by dextran sedimentation (22). Cells were incubated with increasing concentrations of purified rPhl p 5, rPhl p 6, and with an anti-human IgE Ab (E124.2.8 DeZ, ImmunoTech, Marseilles, France). Histamine released into the supernatants was measured by RIA (ImmunoTech).

FIGURE 1. A. Multiple sequence alignment, secondary structure, and solvent accessibility prediction of Phl p 6 variants and group 5 allergens. The amino acid sequences of the mature allergens without their leader peptides were compared. Asterisk lines represent the regions spanned by the Phl p 6 clones; isolated single letters indicate those amino acids that are different from clone 142. Each allergen sequence is preceded by its database entry code (S2101: Phl p 5A, timothy grass; HL5ALLERG: Hol 1 5, velvet grass; MP91_POAAP to MP93_POAAP: Poa p 9 isoforms, Kentucky bluegrass; MPSB_LOLPLR: Lol p 5b, rye grass; MP52_PHAAQ to MP54_PHAAQ: Pha a 5 isoforms, canary grass; MPSB_PHLPLR: Phl p 5B, timothy grass; MPSA_LOLPLR: Lol p 5a, rye grass; and HV06640: Hor v 9, barley); Dashes in the sequences indicate gaps. The sequences were colored to illustrate conserved features in addition to amino acid identity. All glycines and prolines are colored in orange and yellow, respectively. The other residues were colored according to conservation of their physicochemical properties (purple = acidic; blue = hydrophobic; light blue = hydrophobic tendency; red = hydrophobic; green = hydrophilic; white = unconserved). The bottom line displays the predicted secondary structure (SecStructPred), the predicted solvent accessibility (SolAccessPred), and a numbering reference (ruler). In the secondary structure prediction, uppercase letters are used for positions in which accuracy is >86%; H and E indicate residues in α or β conformation, respectively. In the solvent accessibility prediction, uppercase letters are used for residues in which accuracy is >69%; A and B indicate exposed and buried residues respectively. IgE reactivity of rPhl p 6 isoforms and fragments. Nitrocellular filters containing proteins from recombinant Agt 11 phage expressing two Phl p 6 isoforms (c142 and c223), Phl p 6 fragments (c121, c146, c171, c233), and, for control purposes, Agt11 wild-type phage (0) were probed with serum IgE from nine grass pollen-allergic patients (1–9) and from one nonallergic individual (10).
Skin testing

After informed consent was obtained, skin prick tests were performed on the forearms of the individuals as described previously (23). Individuals were pricked with 20-μl aliquots containing different concentrations (1 μg/ml, 10 μg/ml, and 100 μg/ml) of purified rPhl p 6, rPhl p 5, timothy grass pollen extract, histamine, and NaCl (ALK, Horsholm, Denmark).

Analysis of the presence of Phl p 6-related allergens in other grass species and tissue-specific expression of Phl p 6

Protein extracts from pollens, leaves, and roots were obtained by homogenizing the tissues in SDS sample buffer (24). Insoluble materials were removed by centrifuging the extracts (10,000 × g for 20 min; Sorvall RCSC, SS34 rotor). Protein extracts were separated by 14% SDS-PAGE (25) and blotted onto nitrocellulose membranes (26). Nitrocellulose strips were probed with a rabbit anti-celery profilin antiserum, RPI (12), rabbit anti-rPhl p 6 antiserum, and the latter rabbit’s preimmune serum. Bound rabbit Abs were detected with a 1/1000 dilution of 125I-labeled donkey anti-rabbit IgG antiserum (Amersham, Buckinghamshire, U.K.).

In situ localization of Phl p 6 by immunogold electron microscopy

Timothy grass pollen grains were anhydrously fixed as described previously (27). Ultrathin sections were incubated with equal concentrations of either rabbit anti-rPhl p 6 Ig (IgG: protein G-purified Ig fraction) or preimmune IgG. Bound rabbit Abs were detected with goat anti-rabbit IgG Abs coupled to 10-nm-diameter colloidal gold particles (Plano, Wetzlar, Germany) (27).

Results

Isolation and characterization of cDNAs coding for isoforms/fragments of Phl p 6

Six cDNA clones (c142, c223, c171, c121, c233, and c146) coding for Phl p 6 isoforms/fragments were isolated from a timothy grass pollen Agt11 library with serum IgE from a patient allergic to grass pollen (Fig. 1A). The sequences of the described clones have been deposited in the GenBank database (accession numbers: Y16955–Y16960). The deduced amino acid sequence of Phl p 6 (clone 142) contained a 28-aa hydrophobic leader peptide. A molecular mass of 11.8 kDa and an isoelectric point of 5.5 was calculated for the mature Phl p 6 (clone 142) protein, which starts with a glycine residue and shows a high content of alanine residues (20.9%) (Fig. 1A). The computer-aided secondary structure analysis of Phl p 6 indicates a predominant helical content; the calculation of solvent accessibility predicts that many of the N-terminal amino acids are solvent exposed, whereas most of the C-terminal amino acids appeared buried (Fig. 1A). A search for sequence motifs revealed the presence of one potential N-linked glycosylation site (NAS: amino acids 15–17), one N-terminal myristoylation site (GKAT: amino acids 1–4), two cAMP-dependent protein kinase phosphorylation sites (KATT: amino acids 2–5; KYKT: amino acids 33–36), and two peroxisomal targeting sequences (GKA: amino acids 1–3; SKA: amino acids 54–56). The deduced Phl p 6 amino acid sequence displayed identity with a recently submitted Phl p 6 sequence (15) and similarities with the N-terminal portions of group 5 grass pollen allergens (Fig. 1A).

The Phl p 6 N terminus is relevant for IgE binding

Nitrocellulose-bound β-galactosidase-fused complete (c223, c142), N-terminally truncated rPhl p 6 (c171, c121, c233, and c146) and, for control purposes, β-galactosidase alone were exposed to serum IgE from nine grass pollen allergic individuals and a nonallergic person (Fig. 1B). The results obtained showed that the two complete Phl p 6 isoforms and a Phl p 6 fragment lacking only four of the N-terminal amino acids strongly bound IgE from all patients tested that were allergic to grass pollen, and that the IgE binding capacity of the partial Phl p 6 clones decreased depending upon the number of amino acids that were absent from the proteins’ N terminus. A partial clone (clone 121) lacking the N-terminal 30 amino acids had almost completely lost its IgE binding capacity (Fig. 1A and B).

E. coli expression and purification of rPhl p 6: IgE binding capacity of purified rPhl p 6

rPhl p 6 was overexpressed in E. coli BL21 (DE3). A combination of several purification steps yielded pure and soluble rPhl p 6 (~5 mg protein/L. E. coli culture), which was identified by SDS-PAGE as one of the low molecular mass timothy grass pollen allergens (Fig. 2A). MALDI-TOF analysis of purified rPhl p 6 resulted in two mass/charge peaks at 11,790 and 5,896 corresponding with the M1+ and M2H2+ species of the sample, which were in agreement with the deduced Phl p 6 molecular mass (11,789 Da).

rPhl p 6-specific IgE Abs were detected in 128 sera from 171 patients allergic to grass pollen but not in the sera from 10 nonallergic individuals. Preabsorption of sera from patients allergic to grass pollen with rPhl p 6 led to a great reduction of IgE binding to a 10–14 kDa moiety in nitrocellulose-blotted timothy grass pollen extract, indicating that rPhl p 6 and natural Phl p 6 share IgE epitopes. ELISA competition experiments demonstrated that only a small percentage (~20%) of Phl p 5-specific IgE could be preabsorbed with rPhl p 6. IgE binding to rPhl p 1, rPhl p 2, and recombinant timothy grass profilin was not reduced after preincubating sera with rPhl p 6. These results identify Phl p 6 as a major allergen that is distinct from other grass pollen allergens.

rPhl p 6 folds in a stable all α-helical conformation

The far-UV CD spectrum of purified rPhl p 6 (Fig. 2B) indicates that the protein contains a considerable amount of α-helical secondary structure. The spectrum is characterized by two broad minima at 208 nm and 220 nm and a maximum at 191 nm. The secondary structure prediction (Fig. 1A) is in good agreement with the CD measurements, as it indicates predominant α-helical secondary structure content. The unfolding transition of rPhl p 6 is monophasic and is highly cooperative, with a melting point of 61°C. At 85°C, rPhl p 6 assumes a random coil conformation, with a typical minimum at 200 nm. rPhl p 6 shows a high degree of folding reversibility, evident from the cooling curve profile (Fig. 2C) and the far-UV spectrum recorded at 20°C after cooling from 85°C (Fig. 2B).

rPhl p 6 induces dose-dependent basophil histamine release and immediate type skin reactions in patients allergic to grass pollen

Purified rPhl p 6 induced specific and dose-dependent histamine release from basophils of a patient allergic to grass pollen (Fig. 3A). rPhl p 5, which represents a highly active grass pollen allergen (Ref. 14, R. Valenta and S. Flicker, unpublished data), induced maximal release already at a lower concentration compared with rPhl p 6. rPhl p 6, rPhl p 5, and timothy grass pollen extract induced immediate type skin reactions in four patients allergic to grass pollen, but not in the nonallergic individuals (Table I; Fig. 3B). Although no reactions to NaCl were observed, histamine-induced wheal reactions in all individuals tested (Table I; Fig. 3B).

Group 6 allergens represent pollen-specific proteins

Although major groups of grass pollen allergens occur in pollens of most grass species (4), group 6 allergens were reported to occur exclusively in timothy grass (P. pratense) pollen (15). A rabbit anti-rPhl p 6 antisera cross-reacted with group 5 allergens in nitrocellulose-blotted pollen extracts from various monocots (P. pratense, L. perenne, S. cereale, T. sativum, A. sativa, P. communis) between 25 and 28 kDa (Fig. 4A, lane 2). Phl p 6 or Phl p 6-related allergens at 11 kDa were detected exclusively in pollens.
from *P. pratense* and *P. pratensis*. Although a putative N-glycosylation site was found in the amino acid sequence deduced from the Phl p 6 cDNA sequence, the comparable molecular masses observed for natural Phl p 6 and rPhl p 6 exclude heavy glycosylation of natural Phl p 6 (Figs. 2A and 4A). Rabbit anti-rPhl p 6 Abs strongly reacted with Phl p 6 at 11 kDa in nitrocellulose-blotted timothy grass pollen but not with leaf or root extracts (Fig. 4B, lane 2). Profilin was detected in all three tissues at ∼14 kDa (Fig. 4B, lane 1).

**Immunelectron microscopic localization of Phl p 6 in timothy grass pollen**

Using postembedding immunogold electron microscopy, rabbit anti-rPhl p 6 Abs bound to the numerous polysaccharide (P-) particles, which fill much of the interior of a mature timothy grass pollen grain (Fig. 4C). The greatest accumulation of gold particles was observed on sectioned surfaces of the P-particles, indicating that Phl p 6 is present on rather than in the P-particles. Little (cytosol, exine) or no (mitochondria, intine) anti-rPhl p 6 immunoreactivity was observed in other parts of the pollen grain. Likewise, almost no gold particles were detected in the amyloplasts. This localization pattern, taken together with our finding that a rabbit anti-rPhl p 6 antiserum failed to label the P-particles (data not shown), excludes the possibility that the immunolabeling of the P-particles resulted from the presence of cross-reactive group 5 allergens. Control experiments performed with preimmune Ig yielded only a few nonspecifically adsorbed gold particles (Fig. 4D).

**Discussion**

Approximately 40% of allergic patients display immediate type symptoms after contact with grass pollen (3). We have isolated cDNAs coding for isoforms and fragments of a major timothy grass pollen allergen, designated Phl p 6. Phl p 6 represents a 11.8-kDa protein allergen that is recognized by IgE Abs of 75% of patients allergic to grass pollen. The prevalence of IgE recognition of rPhl p 6 is thus in accordance with that reported earlier for natural Phl p 6, indicating that carbohydrate moieties do not play a relevant role in the recognition of Phl p 6 by IgE (28, 29). In agreement with the peptide sequence data obtained for natural Phl p 6, we found that the deduced amino acid sequence of rPhl p 6 shows a high degree of sequence homology with the N-terminal portions of group 5 grass pollen allergens, a family of 25- to 35-kDa major grass pollen allergens (29, 14). Due to the presence of an N-terminal hydrophobic leader peptide, Phl p 6 represents an independent allergen, rather than a group 5 allergen fragment. In agreement with the proposal of other authors, who analyzed a Phl p 6-encoding cDNA clone (15), we suggest that group 5 and group 6 allergens may have evolved from common ancestor genes similar to what was described for group 1 and group 2/3 grass pollen allergens (30). The assumption that Phl p 6 belongs to an independent group of grass pollen allergens is also supported by our finding that Phl p 6 shares few cross-reactive IgE epitopes with group 5 allergens and no epitopes with other grass pollen allergens. The prediction of solvent accessibility indicated that many of the Phl p 6 N-terminal amino acids are solvent exposed, whereas most of the C-terminal amino acid residues appeared to be buried. Although not proof, this finding is in agreement with data obtained from the IgE epitope mapping experiments, which indicate that the protein N terminus is critically involved in IgE recognition. However, it is equally possible that the N terminus itself represents a dominant IgE epitope, or that deletion of the N terminus affects conformational Phl p 6 IgE epitopes.

The expression of Phl p 6 in *E. coli* yielded large amounts of soluble and folded recombinant protein that contained an almost exclusive α-helical secondary structure. The α-helical fold of Phl p 6 is a further confirmation that there are no common structural features that predispose a certain protein to behave as an allergen. Although Phl p 6 is very likely an all-α-helical protein, Bet v 1, the major birch pollen allergen (31) and Bet v 2, birch profilin (32) have a mixed αβ fold. As revealed by CD spectroscopic analysis,
rPhl p 6 shares with other immunologically unrelated pollen allergens (e.g., Bet v 1 (33), Bet v 2 (6, 32)) the remarkable intrinsic tendency to refold into a stable conformation after denaturation. Another feature that is shared by Phl p 6 and other important plant allergens is high expression in pollen tissue. The fact that most of the plant allergens characterized so far are expressed predominantly in mature pollen may therefore be interpreted as a footprint of sensitization via the respiratory tract (34).

**FIGURE 3.** A, rPhl p 6 induces basophil histamine release. Granulocytes from a patient allergic to grass pollen were incubated with various concentrations (x-axis) of purified rPhl p 6 (triangles), Phl p 5 (points), or an anti-IgE mAb (squares). The percentage of histamine released into the supernatant is displayed on the y-axis. Results represent the means (± SD) of triplicate determinations. B, Induction of immediate type skin reactions with rPhl p 6 in sensitized allergic patients. Two patients allergic to grass pollen (LW (a) and HP (b)) and a nonallergic individual (SV (c)) were pricked on their forearms with increasing concentrations of rPhl p 6 and rPhl p 5 as well as with histamine and timothy grass as indicated in d. The wheal area was surrounded with a ballpoint pen.
By immunogold electron microscopy, Phl p 6 was primarily localized on the P-particles of mature pollen. P-particles are small polysaccharide-containing bodies that represent \( \leq 30\% \) of the contents of the dormant pollen grain and, during pollen germination, transfer material into the growing pollen-tube wall (35, 36). The occurrence of Phl p 6 on the P-particles may be of clinical relevance, as P-particles could act as small-sized (\(< 2.5 \mu m\) and therefore respirable allergen-carriers that bring Phl p 6 in immediate contact with the bronchial mucosa. A P-particle-linked intrusion of Phl p 6 into the deeper respiratory tract would thus explain the high prevalence (75\%) of sensitization against this allergen, although only a few grass species (\( P. pratense, P. pratensis \)) contained rabbit anti-rPhl p 6-reactive moieties in the low (10–12 kDa) molecular mass range.

Bound rabbit Abs were detected with a gold-conjugated goat anti-rabbit Ig antiserum (gold particles = black dots). Arrows indicate Phl p 6 immunoreactivity on the P-particles. E, exine; I, intine; P, P-particle; M, mitochondria. The bars represent 0.250 \( \mu m \).
The E. coli-expressed purified rPhl p 6 allergen reacted with IgE Abs of the majority of patients allergic to grass pollen and induced basophil histamine release as well as immediate type skin reactions. It may therefore be used for in vitro as well as in vivo (skin test) diagnoses of grass pollen allergy. Our finding that deletion of the N-terminal portion of Phl p 6 dramatically reduced the IgE binding capacity of the allergen may lead to the construction of hypoallergenic Phl p 6 deletion mutants that may be used for specific immunotherapy of grass pollen allergy with reduced anaphylactic side effects. Recently, the bacterial expression of two hypoallergenic fragments comprising amino acids 1–74 and amino acids 75–160 of the major birch pollen allergen, Bet v 1, was reported (23). The recombinant hypoallergenic Bet v 1 fragments contained most of the Bet v 1-specific T cell epitopes (23) and, upon immunization of animals, induced Abs that blocked IgE binding to the complete Bet v 1 wild-type molecule (S. Vrta and R. Valenta, unpublished data). Our data suggest that for Phl p 6 provide good evidence that it may be possible to use a similar strategy to produce a hypoallergenic N-terminally truncated Phl p 6 version that as such or in combination with a C-terminally truncated Phl p 6 molecule could be used for immunotherapy of Phl p 6-sensitized individuals.

In conclusion, we have produced a major timothy grass pollen allergen, Phl p 6, as a recombinant molecule useful for the in vitro and in vivo diagnosis of grass pollen allergy. Hypoallergenic deletion variants of Phl p 6 may be used for specific immunotherapy of grass pollen allergy.

Acknowledgments

This work is dedicated to Dr. John Heslop-Harrison, a scientific pioneer in the field of pollen biology. We thank Dr. John Seymour (Pat) Heslop-Harrison for critically reading the manuscript. The skillful technical assistance of U. Malkus and G. Kiefermann is gratefully acknowledged. We also thank Dr. Philipp Devillier for providing us with the rabbit anti-celery profilin antiserum (RP1).
