Because histamine receptor type 1 blockade attenuates allergic asthma, we asked whether complete neutralization of histamine by an arthropod-derived, high affinity histamine-binding protein (EV131) would prevent allergic asthma. Intranasal administration of EV131 given before Ag challenge in immunized mice prevented airway hyperreactivity by 70%, and abrogated peribronchial inflammation, pulmonary eosinophilia, mucus hypersecretion, and IL-4 and IL-5 secretion. Saturation with histamine abrogated the inhibitory effect of EV131 on bronchial hyperreactivity. The inhibitory effect of EV131 on bronchial hyperreactivity was comparable to that of glucocorticosteroids. These results demonstrate that histamine is a critical mediator of allergic asthma. Therefore, complete neutralization of histamine, rather than specific histamine receptor blockade, may have a profound effect on allergic asthma. The Journal of Immunology, 2004, 173: 3281–3286.

Allergic asthma is a chronic disease characterized by reversible obstruction of the airways, bronchial hyperresponsiveness (BHR), edema, infiltration of lungs by inflammatory cells, and mucus overproduction (1–3). Allergen-specific Th2 lymphocytes producing IL-4, IL-5, IL-13, IgE, and mucus overproduction are the hallmarks of asthma. In asthmatic individuals, a second contact with the sensitizing allergen results in early and late inflammatory responses. The early reaction is due to IgE-mediated mast cell degranulation, with the release of preformed bioactive molecules such as histamine and 5-hydroxytryptamine, which induce mucus hypersecretion, bronchoconstriction, and increased protein exudation. Although the initial phase may resolve, it is followed by a late-phase response characterized by infiltration of eosinophils and lymphocytes, accompanied by BHR. The repeated exposure to allergens promotes chronic inflammation, leading to the long-term sequelae of asthma.

Histamine, first identified as a potent vasoactive amine, is now recognized for its multiple regulatory activities in the respiratory, digestive, and immune systems, and CNS. Mast cells and basophils are the major producers of preformed histamine that they release from intracellular granules in response to Ag-mediated cross-linking of IgE receptors. Nevertheless, other cells release neo-formed histamine immediately after its synthesis, such as neutrophils, platelets (4), dendritic cells (DCs) (5), and T cells (6), pointing to the important role of this molecule. In lungs, mast cells are present in bronchial walls near vessels, in muscles, and in the bronchial lumen (7). Histamine was one of the first inflammatory mediators of allergic asthma recognized in human and guinea pig models (8).

Interestingly, histamine has been shown to modulate cytokine production in different cell types (9), Ab and T cell responses (10) maintaining a predominant Th2 response in allergic disorders (11). Histamine exerts its effects through four receptor subtypes: histamine receptor 1 (HR1) and HR2, both expressed on lymphoid and nonlymphoid cells; HR3, mainly expressed in the brain (12); and HR4, which has been described recently in leukocytes (13), but is also present in airways (14). However, the role of histamine as a critical effector molecule in a murine model of allergen-induced bronchoconstriction has been questioned, because histamine itself fails to induce direct bronchoconstriction under conditions in which 5-hydroxytryptamine and acetylcholine are effective (15). Furthermore, HR1 antagonists are not recognized as clinically effective therapy against asthma (16).

Although blood-feeding ectoparasites can cause histamine-mediated inflammation in the host, ticks have evolved to suppress inflammation and facilitate feeding by secreting histamine-binding proteins at the site of feeding (17–19). The tick Rhipicephalus appendiculatus secretes three histamine-binding proteins, which have been purified, cloned, expressed, and characterized (20). Their crystallographic structure and biological activity indicate that they sequester histamine, competing with HRs for histamine binding. Both histamine-binding proteins rEV131 and rEV504 bind histamine with high affinity. However, rEV131 has a distinctive feature because it presents a second specific binding site for histamine with lower affinity than the high affinity binding site (20, 21).

In this study, using rEV131, we demonstrate that neutralization of histamine inhibits experimental allergic asthma, suggesting that histamine is a critical mediator in its pathogenesis, and opening new perspectives for asthma therapy.

Materials and Methods

Animals and immunization

The BP2 strain of mice was obtained from Janvier, France (15, 22). The local ethics committee approved all protocols used in this study. The mice, aged 6–8 wk, were immunized s.c. twice at weekly intervals with a 0.4 ml saline containing 100 μg of OVA and 1.6 mg of alum for the initial experiments, and for subsequent experiments the Ag dose was reduced to 1 μg of OVA per injection. One week after the second immunization, at day 14, intranasal challenge was performed under light i.v. ketamine anesthesia by applying 50 μl of OVA in alum-free saline solution (10 μg) or saline alone as a control.

Copyright © 2004 by The American Association of Immunologists, Inc.
The rEV131 protein (340 μg, m.w. 20,406; Evolutes) or budesonide (375 μg, m.w. 430.5; AstraZeneca, Uppsala, Sweden), a potent corticosteroid (positive control), was administered intratracheally (50 μl in saline buffer) under ketamine anesthesia, 1 h before the Ag challenge and/or immediately before the OVA challenge. However, a single administration of BHR (histamine dihydrochloride, m.w. 184; Sigma-Aldrich, St. Louis, MO). The HR antagonists, mepyramine (340 μg, m.w. 402; Sigma-Aldrich), cimetidine (340 μg, m.w. 409; Sigma-Aldrich), and thioperamide (340 μg, m.w. 409; Sigma-Aldrich) were administered intranasally in 50 μl with saline buffer 1 h before the Ag challenge.

Airways resistance

The airways resistance was evaluated by whole-body plethysmography (2). BHR to aerosolized methacholine was investigated at several time points after OVA challenge. Unrestrained conscious mice were placed in whole-body plethysmography chambers (Buxco Electronics, Sharon, CO). Mice were ventilated on high oxygen conditions to avoid hypoxemia induced by methacholine administration. Methacholine at 50 mM was aerosolized for 1 min, and mean airway bronchoconstriction readings, as assessed by enhanced respiratory pause (Penh), were obtained over 15-min periods. Penh can be conceptualized as the phase shift of the thoracic flow and the nasal flow curves; increased phase shift correlates with increased respiratory system resistance.

Penh is calculated by the formula Penh = (Te/RT − 1) × PEF/PFIF, where Te is expiratory time, RT is relaxation time, PEF is peak expiratory flow, and PFIF is peak inspiratory flow.

The mouse is placed in barometric plethysmography with two chambers linked to suction pump, which ensure constant air flow, and PIF is peak inspiratory flow.

The animal is introduced in the first chamber separated from the second in which pressure corresponds to atmospheric pressure. Every compartment is linked to two parts of a differential pressure captor, connected to an electronic amplifier, and signals are analyzed by software. This system allows quantification of many parameters during several respiratory cycles. Penh values correspond to means of 11 events (cycles) every 5 s in raw data. Penh values are indicated for three points before (dotted line) and 5 min correspond to the mean of Penh values between 1 min before and 1 min after the point (e.g., Penh values at +5 min correspond to the mean of all values between point +4 min and point +6 min).

Bronchoalveolar lavage (BAL)

BAL was performed 3 days after intranasal challenge by cannulating the trachea under ketamine anesthesia and washing four times with 0.5 ml each of ice-cold PBS. The lavage fluid was centrifuged, and the supernatant was frozen for cytokine determinations. The cell pellet was resuspended in PBS and counted by a hemocytometer chamber, and cytospin preparations were made using a Shandon cytocentrifuge. The cells were analyzed after differential staining with May-Grunwald-Giemsa.

Lung histology

After BAL, the mice were killed (3 days after OVA challenge). The whole lung was removed and fixed in 4% buffered formaldehyde for standard microscopic analysis H&E and periodic acid Schiff reagent staining. The peribronchial infiltrate and the smooth muscle hyperplasia were assessed by a semiquantitative score (0–3) by two independent observers.

Dosage of IL-4 and IL-5

IL-4 and IL-5 in the BAL fluid were evaluated by ELISA. Briefly, 96-well microtiter plates were coated with monoclonal rat anti-mouse IL-4 (BVD4-1D11; BioSource International, Camarillo, CA) or monoclonal rat anti-mouse IL-5 (R&D Systems, Lille, France) in 0.1 M carbonate buffer, pH 9.2, and incubated overnight at 4°C. Plates were washed and blocked with PBS containing 1% BSA for 2 h. After washing, dilutions of recombinant murine IL-4 or IL-5 or samples were applied overnight at 4°C. Then biotinylated rat anti-IL-4 Ab (BVD6-24G2; BioSource International) or biotinylated rat anti-IL-5 Ab (R&D Systems) was added for 2 h at 4°C. Plates were washed and incubated with ExtrAvidin peroxidase conjugate (at 0.05 μg/ml to each well; Sigma-Aldrich) for 45 min at room temperature. Plates were developed with tetramethylbenzidine substrate (Dynex, Cergy-Pontoise, France). The reaction was stopped with sulfuric acid 2 N, and the plates were read at 450 nm with an automatic microplate reader. The lower limits of detection of these assays are ~10 pg of IL-4/ml sample and 5 pg of IL-5/ml.

Statistical analysis

Data are presented as means and SEM indicated by error bars. Statistical significance was determined by Student’s t test. Values of p < 0.05 were considered statistically significant.

Results

The histamine-binding protein EV131 prevents BHR in Ag-sensitized mice

Because histamine is produced during allergic asthma, we tested the potential interference of the arthropod-derived histamine-binding protein EV131 on BHR. Upon Ag challenge, the mice developed a robust BHR in response to aerosolized methacholine at 24 h (Fig. 1A). Administration of EV131 by the intratracheal route, 1 h and just before OVA challenge, inhibited methacholine-induced bronchoconstriction (70% of controls; p < 0.01). To test whether the inhibitory effect is related to histamine scavenging, we compared histamine-presaturated EV131 and native EV131 on BHR. As expected, the inhibitory effect of presaturated EV131 with a 2-molar excess of histamine was abrogated (Fig. 1B).

EV131 presaturated at equimolar histamine showed loss of activity as compared with native EV131 on BHR of OVA-challenged mice, suggesting that the two histamine pockets are implicated in histamine scavenging.

FIGURE 1. EV131 inhibits OVA-induced BHR in mice sensitized with Ag (A), while histamine-saturated EV131 loses its activity (B). A, BP2 mice were immunized on days 0 and 7 with OVA. The mice were given 50 μl of NaCl (saline) or EV131 (340 μg in NaCl) intratracheally and challenged with 50 μl of NaCl or OVA 1 h later. BHR to methacholine was measured 24 h after challenge by the noninvasive enhanced pause (Penh) and expressed as a function of time. The results represent the mean for two independent experiments (n = 8 mice per group). Inhibition by EV131 and by budesonide is significant at p < 0.01 (**). B, Histamine-saturated EV131 (molar ratio 1 and 2) and native EV131 were given to immunized mice in the identical protocol as described before. Histamine-saturated EV131 (molar ratio 2) lost its inhibitory effect and was significantly different from native EV131 (p < 0.01), while EV131 with histamine at equimolar amounts had partial activity (p < 0.05). Representative results from two independent experiments (n = 4 mice per group).
Therefore, in situ neutralization of histamine by EV131 acting as a soluble receptor with high affinity binding for histamine had a profound effect on BHR, and we therefore asked whether the recruitment of eosinophils during the allergic asthma was influenced.

**Reduction of pulmonary inflammation and of the recruitment of eosinophils by EV131**

Ag challenge caused a substantial recruitment of inflammatory cells into the BAL fluid at 72 h. Administration of EV131 before OVA challenge reduced significantly the numbers of mononuclear cells in the BAL fluid ($p < 0.05$; Fig. 2A). Budesonide had a slightly more pronounced effect ($p < 0.01$; Fig. 2A). Only few eosinophils and neutrophils were found in the BAL fluid of saline-challenged mice. By contrast, the Ag challenge resulted in a significant increase of eosinophil counts in the BAL fluid ($p < 0.01$; Fig. 2B). EV131 administration before the Ag challenge prevented largely the recruitment of eosinophils ($p < 0.01$; Fig. 2B). Furthermore, we demonstrated that the prevention of eosinophil recruitment was due to histamine scavenging, as histamine-presaturated EV131 was ineffective (data not shown). Finally, budesonide had an inhibitory effect on the recruitment of all cell types ($p < 0.01$; Fig. 2B). Representative cytospin preparations of BAL obtained from saline control or OVA-challenged mice in the presence or absence of inhibitors are shown in Fig. 3.

We further investigated the recruitment of eosinophils and other inflammatory cells in lung tissue sections from OVA-sensitized and challenged mice. OVA challenge in immunized mice caused peribronchial cell recruitment and hyperplasia of the bronchial smooth muscle and of goblet cells containing mucus (Fig. 4). Administration of EV131 reduced significantly the peribronchial eosinophilia, mucus hypersecretion, and hyperplasia of bronchial smooth muscles (Fig. 4). Therefore, complete in vivo neutralization of histamine with the high affinity histamine-binding protein EV131 inhibited the inflammatory cell recruitment and suppressed the characteristic allergic inflammation of the airways.

**EV131 reduced IL-4 and IL-5 levels in BAL fluid**

Allergic asthma involves the recruitment of Th2-biased T cells, resulting in increased production of Th2 cytokines. Ag challenge of immunized mice resulted in increased levels of IL-4 and levels of IL-5 (Fig. 5; $p < 0.01$) in the BAL fluid. EV131 given before Ag challenge inhibited significantly IL-4 and IL-5 (Fig. 5; $p < 0.05$) levels. The steroid control budesonide was slightly more effective than EV131 in inhibiting the production of IL-4 and of IL-5 ($p < 0.01$). Therefore, neutralization of histamine with EV131 appears to inhibit the allergen-induced Th2 cytokine response.

**Duration of the inhibitory effect of EV131 on BHR and comparison with HR blockade**

We further investigated the duration of the effect of EV131 on BHR. The inhibitory effect of EV131 was maintained for 48 h after OVA challenge in all mice (Fig. 6A) and, although reduced, was still present at 72 h, when animals received two intratracheal administrations of EV131 (Fig. 6B). Thus, EV131 administered before Ag challenge has a persistent effect.

We finally studied the efficacy of classical HR antagonists in the murine model of allergic asthma. Mepyramine, a selective HR1 antagonist and thioperamide, with mixed HR3 and HR4 antagonistic activity, reduced BHR (Fig. 7). Cimetidine, a classical HR2 antagonist, had no effect on BHR. Therefore, HR1, HR3, and possibly HR4 antagonists have inhibitory effects on BHR, but full inhibition requires on a molar basis larger amounts. Using EV131, which sequesters histamine, may be an interesting and effective alternative approach to inhibit BHR.

**Discussion**

We show in this study that the high affinity histamine-binding protein EV131 prevents experimental allergic asthma, supporting a critical role for histamine in Ag-induced BHR and bronchial inflammation. It is reasonable to assume that EV131 by locally sequestering histamine prevents the access to its receptors.
Histamine plays a critical role in allergic asthma because it induces contraction and hyperplasia of airway smooth muscles, mucus secretion, plasma exudation, and vasodilatation, essentially via HR1 and HR4 (12, 23). Modulation of BHR by HR antagonists in mice has already been reported (24). In agreement with previous observations, we confirm in our system that a high dose of HR1 and HR4 (12, 23). Modulation of BHR by HR antagonists in...
histamine scavenging, we tested presaturated EV131. We showed that the histamine-saturated EV131 lost its inhibitory activity on BHR and eosinophil recruitment.

These findings account for the ability of EV131 to sequester histamine. Indeed, the crystal structure of EV131 reveals two high affinity sites for histamine binding (20). Allergen challenge enhances histamine release upon OVA-specific IgE cross-linking on mast cell and subsequent degranulation with release of histamine in sensitized mice, leading to bronchoconstriction, eosinophilia, and mucus hypersecretion (30). Histamine may also induce maturation of DCs, which polarize naïve CD4+ T cells toward a Th2 phenotype, altering the repertoire of cytokines and chemokines secreted by mature DCs, as compared with DCs that have matured in sensitized mice, leading to bronchoconstriction, eosinophilia, and mucus hypersecretion (30). Histamine may also induce maturation of DCs, which polarize naïve CD4+ T cells toward a Th2 phenotype, altering the repertoire of cytokines and chemokines secreted by mature DCs, as compared with DCs that have matured in sensitized mice, leading to bronchoconstriction, eosinophilia, and mucus hypersecretion (30). Histamine may also induce maturation of DCs, which polarize naïve CD4+ T cells toward a Th2 phenotype, altering the repertoire of cytokines and chemokines secreted by mature DCs, as compared with DCs that have matured in sensitized mice, leading to bronchoconstriction, eosinophilia, and mucus hypersecretion (30).

FIGURE 7. Inhibition of OVA-induced BHR by HR blockade. Inhibition of OVA-induced bronchial hypersensitivity by HR1 antagonist mepramine and by HR2 antagonist thioperamide. Mice were treated with NaCl, mepramine, cimetidine, or thioperamide in 50 μl of NaCl buffer 1 h before challenged with OVA. Penh values were measured 24 h after OVA challenge (n = 8 mice per group). Inhibition by mepramine: p < 0.01 between 3 and 6 min, and thereafter p < 0.05 (*). Inhibition by thioperamide: p < 0.01 between 2 and 6 min, and thereafter p = 0.05 (+).

more than an antagonist at the level of a specific receptor subtype. Furthermore, avoiding the blockade of receptors, such a therapeutic approach could trigger less adverse effects than antagonists and steroids. We show in this study that neutralizing histamine at the early phase may prevent the development of the late phase, and thereby control the asthmatic response.

In conclusion, topical neutralization of histamine in vivo with a high affinity arthropod-derived histamine-binding protein inhibits murine allergic asthma, suggesting a novel therapeutic approach that may be superior to the blockade of single HRs.
