Cyclooxygenase-2 Inhibition Attenuates Antibody Responses against Human Papillomavirus-Like Particles

Elizabeth P. Ryan,* Christine M. Malboeuf,† Matthew Bernard,† Robert C. Rose,‡‡ and Richard P. Phipps*†‡

Vaccinations are responsible for preventing death and disability from infectious disease and are among the most cost-effective and widely used public health interventions (1). However, few vaccines are perfectly safe and many are poorly effective. Side effects from vaccines and poor immune responses to a vaccination, particularly among young children and the elderly, are challenges difficult to overcome. A higher standard of safety is expected of vaccines compared with other medical interventions because vaccines are generally administered to healthy people to prevent disease. As a result, vaccination efforts against bioterror agents (e.g., anthrax) and vaccines in short supply and the threat of bioterrorism. We demonstrate that cyclooxygenase-2 (Cox-2) is crucial for optimal Ab responses to a model vaccine, human papillomavirus type 16 virus-like particles (HPV 16 VLPs). Cox-2-deficient mice produce 70% less IgG, 50% fewer Ab-secreting cells, and 10-fold less neutralizing Ab to HPV 16 VLP vaccination compared with wild-type mice. The reduction in Ab production by Cox-2−/− mice was partially due to a decrease in class switching. SC-58125, a structural analog of the Cox-2-selective inhibitor Celebrex reduced by ~70% human memory B cell differentiation to HPV 16 VLP IgG-secreting cells. The widespread use of nonsteroidal anti-inflammatory drugs and Cox-2-selective inhibitory drugs may therefore reduce vaccine efficacy, especially when vaccines are poorly immunogenic or the target population is poorly responsive to immunization. The Journal of Immunology, 2006, 177: 7811–7819.

were vaccinated with 1 μg of highly purified HPV type 16 VLPs on day 0 and a boost immunization was given on day 14 by i.p. injection (16). Mice were anesthetized with sodium pentobarbital (60 mg/kg) 1, 2, 4, or 6 wk postvaccination. Cardiac puncture was performed to harvest peripheral blood. Whole blood was centrifuged and serum was collected for analysis of Ig levels by ELISA. Spleen and bone marrow cells were harvested and analyzed for the presence of Ab-secreting cells (ASCs) by ELISPOT assay (17).

**VLP production and purification**

Methods used for the construction of recombinant baculoviruses Ac16L1 and Ac16L2 have been described previously in detail (18–20). Purified VLP preparations were free from endotoxin contamination as measured using a commercial assay (E-toxate kit; Sigma-Aldrich), according to the manufacturer’s protocol.

**Culture conditions and reagents**

Splenocytes and bone marrow cells from naïve and HPV 16 VLP-vaccinated mice were cultured in RPMI 1640 (Invitrogen Life Technologies) supplemented with 5% FBS, 5 × 10−5 M 2-ME, 10 mM HEPES, 2 mM L-glutamine, and 50 μg/ml gentamicin. Splenocytes were stimulated with nothing or with recombinant mouse CD40L (21) and/or LPS (5 μg/ml; Sigma-Aldrich). Arachidonic acid (Nu-Chek Prep) was dissolved in 100% ethanol and was diluted to working concentrations in culture medium.

**Small molecule Cox inhibitors**

SC-58125, a highly selective Cox-2 inhibitor, was purchased from Cayman Chemical. SC-58125 was dissolved in DMSO (10 mM stock stored at −20°C) and diluted to working concentrations in culture medium. SC-58125, a highly selective Cox-2 inhibitor, was purchased from Cayman Chemical. SC-58125 was dissolved in DMSO (10 mM stock stored at −20°C) and diluted to working concentrations in culture medium.

**Human memory B cell stimulation**

Frozen PBMCs from individuals vaccinated with bivalent HPV 16/18 VLPs were obtained from the Infectious Disease Unit at the University of Rochester according to institutional review board-approved protocols. PBMCs were stimulated in vitro by a mixture of mitogens as previously described (22, 23). Briefly, 2.5 × 10⁶ PBMCs/200 μl in 96-well round-bottom plates or 5 × 10⁵ PBMCs/ml in 24-well culture plates were cultured in 10% heat-inactivated FBS supplemented RPMI 1640 medium for 5 days (37°C, 5% CO₂). PBMCs were incubated with nothing for 4 h before stimulation. PBMCs were stimulated with Staphylococcus aureus Cowen I strain (SAC; Sigma-Aldrich) (1/1,000), 6 μg/ml CpG 2006 (Integrated DNA Technologies), and pokeweed mitogen (1/100,000) in the presence and absence of the Cox-2-selective inhibitor SC-58125. Pokeweed mitogen was a gift from Dr. S. Crotty (La Jolla Institute of Allergy and Immunology, La Jolla, CA). The number of HPV 16 VLP Ig-secreting cells generated by the mitogen-stimulated PBMCs were analyzed by ELISPOT assay.

**ELISA for HPV 16 VLP Abs**

ELISA plates were coated with 50 ng/well HPV 16 VLPs, HPV 11 VLPs, or PBS alone overnight at 4°C. Plates were blocked with PBS/BSA for 1 h at 20°C. Serial dilutions of sera were incubated for 1 h at 20°C followed by a series of washes in ELISA wash buffer (PBS/Tween 20). Alkaline phosphatase-conjugated goat anti-mouse IgG (or isotype IgM, IgG1, IgG2a IgG2b, IgG3) (Southern Biotechnology Associates) Ab was used to capture VLP-specific Abs and plates were developed with the alkaline phosphatase substrate kit (Bio-Rad). Plates were read at 405 nm on a Bio-Rad Microplate Benchmark plate reader.

**HPV 16 VLP-specific ELISPOT assay**

ELISPOT plates (Millipore) were coated with 50 ng/well HPV 16 VLPs or HPV 11 VLPs (negative control) diluted in PBS, or PBS alone, overnight at 4°C and blocked with RPMI 1640 (5% FBS) for 1 h at 37°C. Serial dilutions of mouse splenocytes and bone marrow cells were incubated for 6 h at 37°C in 5% CO₂. Plates were washed with PBS and further incubated with 1/1000 alkaline phosphatase-conjugated goat anti-mouse IgG Ab.

Serial dilutions of in vitro-stimulated human PBMCs from bivalent HPV 16/18 VLP-vaccinated donors were incubated for 12 h in RPMI 1640 (10% FBS) at 37°C. Plates were then incubated with 1/1000 biotin-labeled goat anti-human IgG (Jackson ImmunoResearch Laboratories) for 2 h at room temperature. After washing four times with PBS/Tween 20, a 1/1000 dilution of streptavidin-conjugated alkaline phosphatase (Bio-Rad) was added for 1 h at room temperature. ELISPOT plates were developed with an alkaline phosphatase substrate kit (Vector Laboratories). ELISPOTs on developed plates were counted using a CTL plate reader and immunospot counting software (Cellular Technologies).

**HPV 16 VLP neutralization assay**

HEK293T cells were cultured in DMEM (10% FBS) to 85% confluence in 48-well microtiter plates. Antisera from HPV 16 VLP-vaccinated mice were examined for their ability to neutralize HPV 16 VLP-DNA complex gene transfer into HEK293T cells (24). One microgram of plasmid DNA (pEGFP-N1; BD Clontech) and 10 μg of HPV 16 VLPs were mixed together in PBS for 30 min at 20°C. Diluted sera (1/10, 1/50, and 1/100 in PBS) from wild-type and Cox-2−/− mice were next incubated with VLP-DNA complex for 30 min at 37°C. The serum, VLP-DNA mixture was added to cells for 3 h at 37°C (5% CO₂). A 1/10, 1/100, and 1/1000 dilution of positive control polyclonal rabbit antisera (HPV 16 VLP) and negative control polyclonal rabbit antisera (HPV 11 VLP) were used in parallel with experimental mouse anti-HPV 11 VLP serum. Supernatant DMEM culture medium was added to cells for 48 h. Cells were analyzed for VLP-DNA gene transfer by fluorescence microscopy using a ×10 objective (with an aperture of 0.30) on an Olympus IX50. DP Controller and DP Manager software (Olympus America) were used for image analysis. Quantitative analysis...
was conducted by flow cytometry (BD Biosciences) using Flow Jo software (Tree Star).

**Flow cytometry**

The percentages of progenitor B cells (pro-B, pre-B, and immature B cells) from wild-type and Cox-2−/− bone marrow were determined by flow cytometry. Following a 20-min preblock with an anti-FcγRI/III/IIR Ab, the CyChrome-anti-mouse CD45R/B220 mAb, biotin anti-mouse CD43, PE anti-mouse CD24, and FITC anti-mouse IgM (all Abs from BD Pharmingen) were used in staining buffer (PBS, 0.1%BSA, NaN₃) at predetermined concentrations with isotype-matched Abs. CyChrome anti-mouse B220 and FITC anti-mouse CD3 mAbs were used to determine the percentage of T and B lymphocytes in spleen from HPV 16 VLP-vaccinated mice. B cell class switching was analyzed in spleens of wild-type and Cox-2−/− mice using FITC-conjugated anti-IgG1 (A85-1), anti-IgG2a (R19-15), anti-IgG2b (R12-3), and anti-IgG3 (R40-82) (BD Pharmingen) (25). Cells were analyzed by flow cytometry (BD Biosciences) using Flowjo software (Tree Star).

**Statistical analysis**

All data are presented as mean ± SEM. Two-tailed Student’s t tests were used for comparisons of two groups, and one-way ANOVA was used for comparison of three or more groups with Excel software (2003). In all cases, p values of <0.05 were considered statistically significant.

**Results**

**VLP Ab production is impaired in Cox-2−/− mice**

We first examined the role of Cox-2 in the generation of the humoral immune response to HPV 16 VLPs by vaccinating wild-type and Cox-2−/− mice with HPV16 VLPs (1 μg; i.p. injection, without adjuvant). Levels of anti-HPV 16 VLP-specific Abs in sera of mice were measured by ELISA on days 7, 14, and 28 postvaccination. Significant (~5-fold) reductions in anti-HPV 16 VLP IgG were detected as early as days 7 and 14 postvaccination (Fig. 1A, p < 0.05). In contrast to wild-type mice that produce a robust increase in anti-HPV 16 VLP IgG, with a reciprocal end point titer of 10,000/1,875 by day 28 postvaccination, Cox-2−/− mice produced a reciprocal end point titer of only 2,975/585. This 70% reduction in Cox-2−/− mouse Ab production supports the importance of Cox-2 in the generation of humoral immune responses against HPV 16 VLPs. IgG subtype analysis in Cox-2−/− mice revealed that HPV 16 VLP-specific IgG1 was reduced by ~69%, IgG2a by ~89%, IgG2b by ~10%, and IgG3 by ~43% (Fig. 1B). Cox-2−/− mice showed >4-fold increase in IgM and no IgE was detected (data not shown).

To address a possible role for a defect in early B cell development in Cox-2−/− mice, we compared the ratio of different B cell subsets (pro-B, pre-B, and immature B) in the bone marrow of naive wild-type and Cox-2−/− mice. The proportions of B cell subsets in the bone marrow were similar and no differences were detected in the percentage of B220-positive B cells and CD3-positive T cells in spleen (data not shown). Therefore, changes in existing B cell precursors did not influence the marked reduction in Ab production by Cox-2−/− mice following vaccination.
Vaccinated Cox-2−/− mice have fewer HPV 16 VLP-specific ASC

We next determined the frequency of HPV 16 VLP-specific ASCs following vaccination (17). The number of HPV 16 VLP IgG-secreting cells was first measured in the spleen and bone marrow of vaccinated mice to determine whether the reduction in sera anti-HPV 16 VLP IgG levels seen in Cox-2−/− mice was due to differences in the number of ASCs. Fig. 2A shows a reduction in the number of spots from HPV 16 VLP IgG-secreting cells in Cox-2−/− spleen on days 7, 14, and 28 postvaccination compared with wild-type spleen. Given that the initial humoral response occurs in the spleen and long-term Ab synthesis occurs in the bone marrow (26), we next sought to determine whether any differences may exist in the number of bone marrow HPV 16 VLP IgG-secreting cells in Cox-2−/− vs wild-type mice. Fig. 2B demonstrates that there were markedly fewer spots and decreased mean spot size in the Cox-2−/− mice bone marrow on days 14 and 28 postvaccination. Significant differences were detected in the kinetics of HPV 16 VLP IgG-secreting cells from spleen and bone marrow of wild-type and Cox-2−/− mice 1, 2, and 4 wk postvaccination (Fig. 2C, p < 0.05). Cox-2−/− spleen had ~80% fewer ASCs on day 7, with ~50 and ~60% less ASCs on days 14 and 28 postvaccination. There was ~40–50% fewer ASCs in the bone marrow on days 14 and 28 postvaccination in Cox-2−/− mice compared with wild type.

To evaluate the isotypes responsible for the reduction in IgG-secreting cells, we determined the number IgG1-, IgG2a-, IgG2b-, and IgG3-secreting cells in the spleen of vaccinated wild-type and Cox-2−/− mice (Fig. 3A). Consistent with our findings of elevated IgM production, there were significantly more IgM-secreting cells in Cox-2−/− mice (p < 0.03). However, as shown in Fig. 3B, there were ~78% fewer IgG1, ~70% fewer IgG2a, ~15% fewer IgG2b, and ~55% less IgG3-secreting cells in spleen of Cox-2−/− mice as compared with wild type on day 28 postvaccination (p < 0.02). Large reductions in mean spot sizes for the IgG1 isotype was seen in Cox-2−/− mice supporting another mechanism by which Cox-2 can regulate Ab production. These findings demonstrate that, in addition to a reduction in ASC number, each plasma cell was secreting less Ig, thus further contributing to reduced serum Ab.

We next examined the number of class switched B cells in the spleen to determine whether the reduction in Ig isotype-secreting cell number in the Cox-2−/− mice was due to a defect in class switch recombination. The data in Fig. 4 demonstrate that there was a ~34% reduction in B220+ IgG1− cells and ~50% fewer B220+ IgG2a− cells on day 21 postvaccination in the Cox-2−/− compared with wild type. No differences in the percentage of
IgG2b and IgG3 class switched B cells were detected. These data support that the Cox-2\(^{-/-}\) mice exhibit altered B cell class switch recombination to certain IgG isotypes that contributes to the decreased number of ASCs after HPV 16 VLP vaccination.

**HPV 16 VLP-specific neutralizing Ab titers are reduced in Cox-2\(^{-/-}\) mice**

Prevention of HPV infections has been convincingly achieved by HPV genotype-specific neutralizing Abs alone (27, 28). Virus neutralization activity of Abs in sera of vaccinated wild-type and Cox-2\(^{-/-}\) mice was assessed using an in vitro assay as previously described (24). HPV 16 VLPs mediate entry of plasmid DNA-expressing GFP into HEK293T cells after 48 h (24). A 1/10 dilution of VLP-vaccinated wild-type mouse sera harvested on day 28 postvaccination was sufficient to completely prevent VLP-mediated DNA gene transfer with partial neutralization on day 14 (Fig. 5A). In contrast, the anti-sera from Cox-2\(^{-/-}\) mice harvested on days 14 and 28 postvaccination showed a markedly reduced ability to neutralize VLP-DNA gene transfer into HEK293T cells compared with wild type. No significant differences in neutralization between wild type and Cox-2\(^{-/-}\) were measured on day 7 postvaccination. A dramatic reduction in the neutralizing capacity of Cox-2\(^{-/-}\) antisera harvested 6 wk postvaccination was seen at the 1/10 (80% decrease) and 1/50 (50% decrease) dilution of sera when compared with wild-type antisera (Fig. 5B). These findings are consistent with the reduction in serum anti-HPV 16 VLP IgG levels (Fig. 1) and the fewer HPV 16 VLP ASCs in the bone marrow and spleen (Figs. 2 and 3) of Cox-2\(^{-/-}\) mice.

We next quantified the differences in the ability of wild-type and Cox-2\(^{-/-}\) antisera to neutralize VLP-DNA complex gene transfer by comparing the mean fluorescence intensity of GFP-expressing HEK293T cells as detected by flow cytometry. The higher fluorescence intensity corresponds to a reduced ability to neutralize VLP-mediated DNA entry. The wild-type antisera showed a 2-fold increase in neutralization of DNA entry after 2 wk with 10- and 5-fold increases at 4 and 6 wk, compared with Cox-2\(^{-/-}\) (Fig. 5C). These data strongly support the importance of Cox-2 for optimal production of HPV 16 VLP-neutralizing Ab responses.

**Cox-2 inhibition impairs HPV 16 VLP IgG-secreting cell production and secretion**

Long-lived plasma cells and memory B cells are responsible for long-term humoral immunity elicited by most vaccines (17, 29). Following the finding that VLP neutralization titers were reduced in VLP-vaccinated Cox-2\(^{-/-}\) mice, we determined whether there were changes in HPV 16 VLP memory B cell expansion in vitro. The memory B cell response is a central component of humoral immunity to vaccination as memory cells are responsible for driving the robust Ab response after re-exposure to Ag (22). The ex vivo generation of ASCs from memory B cells found in spleen of HPV 16 VLP-vaccinated mice requires splenocyte stimulation for 4 days with LPS plus 10 \(\mu\)g/ml HPV 16 VLPs. There was a modest increase in the number and spot size of ASCs generated by wild-type and Cox-2\(^{-/-}\) splenocytes harvested on day 28 postvaccination when compared with day 14. Fig. 6A shows that there were ~50% fewer HPV 16 VLP IgG-secreting cells generated in the...
Cox-2-deficient mice vs wild type as determined by spot number \( (p < 0.04) \). These in vitro results expand upon the in vivo findings, and support that Cox-2 is important for B cells to differentiate into ASCs. Moreover, significant (20%) reductions were measured in mean spot size of in vitro-generated Cox-2\(^{-/}\) Ig-secreting cells on day 28 postvaccination compared with wild-type mice indicating that some Cox-2\(^{-/}\) cells were secreting less Ig than wild-type mice (Fig. 6B, \( p < 0.05 \)). These findings reveal that the combined reduction in total spot number (50% decrease) and mean spot size (20% decrease) of Cox-2\(^{-/}\) HPV 16 VLP IgG-secreting cells contributed to the 70% reduction in serum anti-HPV 16 VLP IgG levels (see Fig. 1A) on day 28 postvaccination.

The findings of significantly reduced production of ASCs by Cox-2\(^{-/}\) splenocytes prompted us to next investigate the effects of pharmacological Cox-2 inhibition on Ag-specific Ig-secreting cell formation in vitro. Wild-type splenocytes stimulated with LPS plus HPV 16 VLP in the presence and absence of the Cox-2-selective inhibitor, SC-58125, for 4 days, were used to determine the frequency of HPV 16 VLP IgG-secreting cell production.

LPS plus HPV 16 VLP-stimulated splenocytes incubated with SC-58125 showed a dose-dependent reduction in the frequency of HPV 16 VLP IgG-secreting cells (Fig. 6C). Treatment with 10 \( \mu \)M SC-58125 resulted in a modest decrease, with significant 50 and 75% reductions in the number of HPV 16 VLP-specific IgG-secreting cells at the 20 and 40 \( \mu \)M, respectively (Fig. 6D, \( p < 0.05 \)). The Cox-2\(^{-/}\) splenocytes generated similar reductions in HPV 16 VLP IgG-secreting cell production as the 40 \( \mu \)M Cox-2 inhibitor-treated cells when compared with wild type.

**Cox-2 inhibition reduced human memory B cell expansion to HPV 16 VLP IgG-secreting cells**

We next investigated whether human memory B cell expansion was altered following Cox-2-selective inhibition. PBMCs from HPV 16 VLP-vaccinated individuals were stimulated in vitro with a mixture of mitogens in the presence and absence of the Cox-2-selective inhibitor, SC-58125, for 5 days. The number of HPV 16 VLP-specific IgG-secreting cells was determined by ELISPOT assay (23). No spots were detectable by unstimulated PBMCs. Fig. 7A shows that Cox-2-selective inhibition reduced the number of HPV 16 VLP IgG-secreting cells produced by restimulated human memory B cells from three vaccinated individuals. There was a significant dose-dependent reduction in the number of HPV 16 VLP IgG-secreting cells when PBMCs were treated with the Cox-2-selective inhibitor, SC-58125 (Fig. 7B, \( p < 0.01 \)). Mitogen-stimulated PBMCs treated with 5 \( \mu \)M SC-58125 produced \( \sim 50\% \) fewer HPV 16 VLP IgG-secreting cells and >5-fold reductions in spot number were detected by cells treated with 10 \( \mu \)M and 20 \( \mu \)M SC-58125. Sample nos. 1 and 2 had larger mean spot sizes of HPV 16 VLP-secreting cells than sample no. 3. However, only sample no. 3 showed marked reductions in mean spot size in the presence of the Cox-2-selective inhibitor compared with vehicle-treated cells. These new findings support those herein showing reduced humoral responses in HPV 16 VLP-vaccinated Cox-2\(^{-/}\) mice. These results confirm that Cox-2 is critical for optimal HPV 16 VLP-specific Ab production by influencing human memory B cell expansion to ASCs.

**Discussion**

In this report, we show that Cox-2 is essential for optimal humoral immune responses against HPV type 16. These new findings reveal that Cox-2-deficiency impairs neutralizing Ab production following HPV 16 VLP vaccination. These data have important implications regarding the use of NSAIDs and Cox-2-selective inhibitors during vaccination. Drugs that inhibit Cox-2 are widely used for relief of symptoms of pain and inflammation associated with vaccination and other inflammatory conditions. Our findings reveal that the combination of reduced class switch recombination, B cell differentiation to ASCs and Ig secretion are responsible for impaired Ab production by HPV 16 VLP-vaccinated Cox-2\(^{-/}\) mice. The defect in Ab production by Cox-2\(^{-/}\) mice resulted in a dramatic reduction in VLP-specific neutralizing Ab titers (Fig. 5). We demonstrated that Cox-2 is required for B cells to optimally differentiate into HPV 16 IgG-secreting cells by using an Ag-specific ELISPOT assay that detects the number of HPV 16 VLP IgG-secreting cells generated in the spleen and bone marrow of HPV 16 VLP-vaccinated wild-type and Cox-2\(^{-/}\) mice (Fig. 2). The large \( (\sim 50\%) \) reduction in the number of HPV 16 VLP IgG-secreting cells in Cox-2\(^{-/}\) mice supports our findings of reduced HPV 16 VLP-specific IgG in serum (Fig. 1). These data showing that Cox-2 is critical for optimal production of neutralizing Ab in vivo, together with other reports confirming that Abs serve as a major protective component against HPV type 16 infections, suggest the
potential for adverse effects of NSAIDs and Cox-2-selective inhibitors during HPV 16 VLP vaccination in humans.

HPV 16 VLPs can elicit both T cell-dependent and T cell-independent responses based on reports showing that VLP-immunized CD4 knockout mice can generate Ab responses and that VLPs directly bind and activate B cells via the BCR and TLR-4 (25, 30). Furthermore, HPV 16 VLPs were shown to directly activate class switch recombination in B cells via a MyD88-dependent pathway (25). Cox-2 is a well-documented downstream target of MyD88 signaling as MyD88 induces nuclear translocation of NF-κB and CREB, which then bind to consensus sequences in the Cox-2 promoter to increase transcription of Cox-2 (31–34). We speculate that Cox-2 levels are dramatically reduced in MyD88-deficient mice and that lower Cox-2 activity contributed to the decreased Ab response seen by MyD88-deficient mice to HPV 16 VLP vaccination. Our findings of reduced IgG1- and IgG2a-positive B cells (Fig. 4) also support earlier research from our laboratory showing that the Cox product, PGE2, is vital for optimal Ig class switching (35, 36). The elevated IgM levels further support the hypothesis that without Cox-2, mouse B cells have difficulty undergoing class switching.

Recent reports have shown enhanced type-1, cytotoxic T cell responses following Cox-2 inhibition (37, 38). In contrast to the goal of increased production of infection-fighting Abs following HPV 16 VLP vaccination, cancer vaccine strategies attempt to elevate IFN-γ production and promote the generation of CD8-positive CTLs that exhibit potent antitumor activity. The emerging concept that elevated tumor Cox-2 levels contribute to a humoral immune response as a mechanism to evade immune surveillance are consistent with our hypothesis that Cox-2 helps the host to generate Ag-specific type-2 immunity enabling rapid production of neutralizing Abs to control infection. However, we speculate that the loss of Cox-2 in T cells may also contribute to the reduced Ab response by HPV 16 VLPs and that there may be a spectrum of dependence for Cox-2 activity during Ab responses to T cell-dependent and T cell-independent Ags. Moreover, the loss of Cox-2 by plasma cells may also contribute to reduced Ab production by the Cox-2−/− mice as Cox-2 can be expressed in human plasma cells (data not shown) and multiple myeloma cells (39, 40). Future investigations that include a comprehensive analysis of the immune phenotype of Cox-2−/− mice and an analysis of the potential compensatory mechanisms in lymphocytes will advance our understanding of the role of Cox-2 in humoral immune responses.

The primary goal of vaccination is to enhance the rate of Ab production following re-exposure to Ag such that one will effectively neutralize infection. Accurate measurements of memory B cell recall responses have recently contributed to improving vaccination strategies against infectious agents (e.g., smallpox, anthrax). We assessed the role of Cox-2 in a memory B cell recall Ag response assay using vaccinated wild-type and Cox-2−/− mice splenocytes in vitro. HPV 16 VLP memory B cells rapidly generate HPV 16 VLP-specific Ig-secreting cells in response to polyclonal stimuli plus Ag re-exposure (23). This approach was used to determine whether or not impaired memory B cell expansion was
a mechanism for reduced Ab production by Cox-2−/− mice. Interestingly, we found a significant reduction in the number of HPV 16 VLP-specific ASCs generated (Fig. 6A) and a decrease in the amount of Ig secreted by Cox-2−/− ASCs compared with wild type (Fig. 6B). These findings suggest that Cox-2 deficiency influences the ability of memory B cells to produce Ab postvaccination, and further suggests that Cox inhibitory drugs may pose untoward effects on Ab production in vaccinated individuals treated with Cox-2-selective inhibitors warrant a detailed evaluation of the practice of using NSAIDs during vaccination strategies in humans.

**Acknowledgments**

We thank Dr. Richard Reichman from the Infectious Disease Unit at the University of Rochester for providing PBMCs from bivalent HPV 16/18 VLP-vaccinated individuals and Dr. Kerry O’Banion for his comments and review of this manuscript.
