Metformin Attenuated the Autoimmune Disease of the Central Nervous System in Animal Models of Multiple Sclerosis

Narender Nath,* Musfiquidin Khan,* Manjeet K. Paintlia,* Md Nasrul Hoda,* and Shailendra Giri2†

Experimental autoimmune encephalomyelitis (EAE) is a T cell-mediated autoimmune disease of the CNS. Metformin is the most widely used drug for diabetes and mediates its action via activating AMP-activated protein kinase (AMPK). We provide evidence that metformin attenuates the induction of EAE by restricting the infiltration of mononuclear cells into the CNS, down-regulating the expression of proinflammatory cytokines (IFN-γ, TNF-α, IL-6, IL-17, and inducible NO synthase (iNOS)), cell adhesion molecules, matrix metalloproteinase 9, and chemokine (RANTES). Furthermore, the AMPK activity and lipid alterations (total phospholipids and in free fatty acids) were restored by metformin treatment in the CNS of treated EAE animals, suggesting the possible involvement of AMPK. Metformin activated AMPK in macrophages and thereby inhibited biosynthesis of phospholipids as well as neutral lipids and also down-regulated the expression of endotoxin (LPS)-induced proinflammatory cytokines and their mediators (iNOS and cyclooxygenase 2). It also attenuated IFN-γ and IL-17-induced iNOS and cyclooxygenase 2 expression in RAW267.4 cells, further supporting its anti-inflammatory property. Metformin inhibited T cell-mediated immune responses including Ag-specific recall responses and production of Th1 or Th17 cytokines, while it induced the generation of IL-10 in spleen cells of treated EAE animals. Altogether these findings reveal that metformin may have a possible therapeutic value for the treatment of multiple sclerosis and other inflammatory diseases.

Received for publication October 24, 2008. Accepted for publication April 7, 2009.

FIGURE 1. Metformin attenuates the EAE disease process in SJL and C57BL/6 mice. Active EAE was induced in SJL or C57BL/6 mice with immunization of 100 μg of peptides PLP<sub>139–151</sub> or MOG<sub>35–55</sub> on days 0 and 7. A and B, Metformin was given at 20, 50, or 100 mg/kg by the oral route once daily starting day 0 of immunization. C, Metformin was given by the oral route three times a day starting on day 0 of immunization in a total of 100 mg/kg. D and E, Metformin in C57BL/6 mice was given by the oral (D) and i.p. (E) routes at 100 mg/kg daily divided in three doses. F, To examine the therapeutic efficacy, metformin was administered to ongoing active EAE in SJL mice, starting on day 14 (when all the mice had visible clinical symptoms of disease; 2.74 ± 0.27) at 100 mg/kg by the oral route and given once daily. The clinical symptoms were scored every day in a blinded manner. Data points are presented as the mean ± SEM. Values of p < 0.01, p < 0.05, and NS refer to vehicle-treated EAE mice (two-way ANOVA). Numbers of mice used in the study are summarized in Table I.

animals were housed in the pathogen-free animal facility of Medical University of South Carolina (Charleston, SC). All animal protocols were approved by the Animal Care and Use Committee of the Medical University of South Carolina. Paralyzed mice were afforded facile access to food and water.

**Reagents and cell line**

Myelin proteolipid protein peptide (PLP<sub>139–151</sub>) (HSLGKWLGHPDKF) and MOG<sub>35–55</sub> (MEVGWTRSPFSVRVHLYRNGK) were purchased from Peptide International. Metformin was purchased from Sigma-Aldrich. The anti-phospho-ACC (Ser79) and phospho-AMPKα (Thr172) were purchased from Cell Signaling. Abs for iNOS, Cox2, and β-actin were purchased from Santa Cruz Biotechnology. Mouse IFN-γ and mouse IL-17 recombinant proteins were purchased from R&D Systems. The macrophage cell line (RAW267.4) was purchased from American Type Culture Collection (Rockville, MD). The macrophage cell line (RAW267.4) was purchased from American Type Culture Collection (Rockville, MD). The macrophage cell line (RAW267.4) was purchased from American Type Culture Collection (Rockville, MD). The macrophage cell line (RAW267.4) was purchased from American Type Culture Collection (Rockville, MD). The macrophage cell line (RAW267.4) was purchased from American Type Culture Collection (Rockville, MD).

**Active EAE induction in SJL and C57BL/6 mice**

Mice were immunized on day 0 by s.c. injections in the flank region with 100 μl of an emulsion of PLP<sub>139–151</sub> (SJL) and MOG<sub>35–55</sub> (C57BL/6) peptide in CFA. The final concentrations of peptide and *Mycobacterium tuberculosis* H37Ra were 100 and 200 μg/mouse, respectively. Each mouse additionally received 200 ng of pertussis toxin (Sigma-Aldrich) by i.v. injection in 300 μl of PBS on day 0 and 72 h after the first immunization. Clinical disease was monitored daily in a blinded fashion by measuring paralysis according to the following conventional grading system: 0, no disease; 2, loss of tail tonicity; 2.5, partial hind limb paralysis (uneven gate of hind limb); 3, complete hind limb paralysis; 4, complete hind and forelimb paralysis; and 5, moribund or dead. Clinical disease scores are presented as the average maximal scores over the treatment period (mean ± SD) and were analyzed using the Kruskal-Wallis test.

**Administration of metformin**

The mice were administered metformin (20–100 mg/kg body weight in saline by oral gavage) every day from day 0 to until the end of the study (100 μl/mouse, one or three times in a day with total 20, 50, or 100 mg/kg of drug) or i.p., as indicated following the induction of active EAE disease. Saline as a vehicle (200 μl) was given to untreated EAE animals.

**Histology**

To assess the infiltration of immune cells in the CNS, the C57BL/6 mice in treated and untreated groups were killed at the peak of EAE disease (day 16) by CO2 asphyxiation. The lumbar region of the spinal cords were taken out and fixed in 10% buffered formalin. Paraffin-embedded, 4-μm-thick transverse sections of spinal cord (six sections per mouse) were stained with H&E to assess leukocyte infiltration and inflammation using an Olympus Compound Microscope (Olympus BX-60) with digital camera attached. The spinal cord sections from five representative animals (untreated and metformin treated) were processed and stained with Hoechst 33342 dye (for nuclei stain). Images of the various regions of the spinal cord were taken by fluorescence microscopy. Infiltrating cells labeled with Hoechst were analyzed using Image-Pro-Plus 4.0 (Media Cybernetics) software and plotted. Individual sections were analyzed and the mean and SD were calculated for each group (n = 5).

**AMPK activity**

AMPKα activity was assayed in total brain homogenate of metformin-treated and vehicle-treated EAE animals. In brief, brain was homogenized in lysis buffer (50 mM Tris-HCl (pH 7.4) containing 50 mM NaCl, 1 mM EDTA, 0.5 mM EGTA, 10% glycerol, and a protease inhibitor mixture). Approximately, 200 μg of cell lysate was incubated with anti-AMPKα1 Ab (Cell Signaling) for 2 h, then 30 μl of protein A/G plus agarose was added and incubated for an additional 1 h at 4°C. The immune complexes were washed twice in lysis buffer and twice in kinase buffer (62.5 mM...
HEPES (pH 7.0), 62.5 mM NaCl, 62.5 mM NaF, 62.5 mM sodium pyrophosphate, 1.25 mM EDTA, 1.25 mM EGTA, and 1 mM DTT) and incubated at 30°C in 30 μl of kinase assay buffer containing 200 μM AMP and ATP mixture (200 μM ATP and 1.5 μCi of [γ-32P]ATP), with acetyl CoA carboxylase (ACC) recombinant protein (Upstate Biotechnology) for 20 min. The reaction was terminated by adding sample buffer followed by boiling for 3 min. Samples were loaded onto a SDS-PAGE 4–20% Tris-glycine gel and transferred onto nitrocellulose membranes followed by exposure on x-ray film (ECL Hyper film; Amersham Life Science).

Recall responses

Myelin MOG35–55-immune spleen cells (2 × 10^6/100 μl/well) isolated from treated and untreated groups with metformin were cultured in 96-well, round-bottom microculture plates (Falcon Labware) in 0.1 ml of RPMI complete medium in the presence of 10% FCS. IL-2, IL-4, IL-5, IL-6, IL-10, and IL-17 were determined using the ELISA OptEIA system (BD Pharmingen and R&D Systems) as per the manufacturer’s instructions.

Isolation of splenic macrophages

The 8- to 10-wk-old female C57BL/6 mice were killed and spleens were taken out. The spleens were lyzed and prepared as single-cell suspensions followed by removal of all of the RBC with 1× plasma lysed (BD Biosciences). The cells were washed twice and resuspended in RPMI 1640 and the concentration adjusted to 5 × 10^5 cells/ml total spleen cells was plated in 24- and 6-well tissue culture plates and incubated at 37°C for 2 h. After 2 h, the nonadherent (mostly lymphocytes) cells were removed and adherent cells (96% macrophages) were washed twice with RPMI 1640 and finally resuspended in RPMI 1640. The macrophages were pretreated with different concentrations of metformin (5–10 mM) for 2 h followed by stimulation with LPS (1 μg/ml) for 48 h. The production of NO and proinflammatory cytokines (IFN-γ, TNF-α, and IL-6) and expression of iNOS and Cox2 was determined by ELISA and immunoblot, respectively (28–30).

RNA analysis and real-time PCR (quantitative PCR)

Total cellular RNA from brains of control, untreated EAE, or metformin-treated EAE or CD3-positive total T cells, as indicated, were isolated using TRIzol reagent (Favitech) per the manufacturer’s protocol. cDNA synthesis was performed using an iScript cDNA synthesis kit (Bio-Rad) according to the manufacturer’s protocol. RT-PCR was performed with SYBR Green PCR master mix (Bio-Rad) and Bio-Rad iCycler iQ PCR using the following primers: mouse IFN-γ sense, GCA TTC ATG AGT ATT GCC AAG and antisense, GGT GGA CCA CTC GGA TGA; TNF-α sense, CAT CTC TTC CTA AAT CCA A and antisense, TGG CAG TAG TAC ACA AGG and antisense.

**FIGURE 2.** Metformin (Met) restricts infiltration of mononuclear cells into the CNS of treated EAE animals. Active EAE was induced in the C57BL/6 mice with MOG35–55 and one group was treated with metformin orally three times a day (100 mg/kg daily) as described in Materials and Methods. At the peak of disease (day 16), animals were killed and spinal cords were harvested for infiltration studies. Infiltration of mononuclear cells in spinal cords sections were examined by H&E stain (A) and by Hoechst 33342 dye (for nuclei stain) (B) in various regions of the spinal cord like artery, border, and bottom and central canal. C, Representative bar graphs of the nuclei count in different regions of spinal cords for comparison. **+,** p < 0.001 compared with metformin-treated and EAE-un-treated mice (n = 5).
GCA CAT GAG GAC TTG TAG GT; T-bet sense, CAA CAA CCC CTT TGC CAA AG and antisense, TCC CCC AAG CAG TTG ACA GT; retinoid-related orphan receptor gamma (RORγt) sense, CCG CTG AGA GGG CTT CAC and antisense, TGC AGG AGT AGG CCA CAT TAC A; and HPRT (hypoxanthine phosphoribosyltransferase) sense, GCT TTC CCT GGT TAA GCA GTA CA and antisense, CAA ACT TGT CTG GAA TTT CAA ATC. Thermal cycling conditions were as follows: activation of DNA polymerase at 95°C for 10 min, followed by 40 cycles of amplification at 95°C for 30 s and at 63.0°C for 30 s.

Immunoblot analysis

Primary macrophages and RAW267.4 cells were incubated in the presence or absence of various concentrations of metformin as indicated in the figure legends followed by lysis in lysis buffer (50 mM Tris-HCl (pH 7.5), 250 mM NaCl, 5 mM EDTA, 50 mM NaF, and 0.5% Nonidet P-40) containing a protease inhibitor mixture (Sigma-Aldrich). Proteins were resolved by SDS-PAGE and transferred onto nitrocellulose membranes. The membrane was then blocked for 1 h in 5% nonfat dry milk and TTBS (20 mM Tris, 500 mM NaCl, and 0.1% Tween 20, pH 7.5) and incubated overnight in primary antisera (phospho-ACC, iNOS, Cox2, and β-actin) containing 5% nonfat dry milk or 5% BSA in the case of phospho-Alf. Blots were washed with TTBS (four times, 5 min each) and incubated for 45 min at room temperature with HRP-conjugated anti-rabbit or anti-mouse secondary Ab at a dilution of 1/5000. The blots were washed three times in TTBS and developed with an ECL-Plus Detection System (28–31).

Fatty acid and cholesterol biosynthesis

Treated macrophage cells were preincubated in complete medium with [2-14C]acetate (5 μCi/well). After 4 h the indicated time, the cells were processed for lipid extraction and incorporation of labeled acetate in fatty acid and cholesterol was analyzed as mentioned previously (28, 31, 32).

Brain extract from various groups were processed for lipid extraction as previously described (28, 31, 32).

Statistical analysis

GraphPad Prism software was used throughout for statistical analysis. The Kruskal-Wallis test and Student’s t test were used to analyze clinical disease score. Statistics for Hoechst-stained nuclei, cell proliferation, and cytokine responses were analyzed with one-way ANOVA and Student’s t test. Significances (p) between groups were determined using the Newman-Keuls test. A value of p ≤ 0.05 and above was considered significant.

Results

Metformin attenuates EAE disease progression in chronic EAE mice models

To evaluate the efficacy of metformin, EAE was induced in SJL mice with myelin PLP139–151 peptide (100 μg/mouse). The mice developed clinical symptoms of EAE disease from day 10 ± 0.8 (Fig. 1A) and reached a maximum mean clinical score of 3.4 ± 0.21 on day 17. To test the prophylactic efficacy in EAE, metformin was given orally as 20, 50, or 100 mg/kg starting from day 0 of immunization. Compared with the untreated EAE group, metformin treatment with 20 or 50 mg/kg did not provide any significant protection in disease induction (Fig. 1A). However, at the dose of 100 mg/kg, it provided promising results, especially at the chronic phase of disease (p < 0.05; Fig. 1B). The reason for lower efficacy of metformin at 100 mg/kg could be due to the fast clearance from the body when given once a day; therefore, we decided
to give metformin three times a day in a 100-μl volume each time with a total dose of 100 mg/kg. Following this regimen, we observed a significant delay of onset and disease attenuation (p < 0.01; Fig. 1C and Table I).

Similarly, active EAE disease was induced with immunization of MOG35–55 peptide (100 μg/mouse) in C57BL/6 mice and metformin was given orally or by the i.p. route three times daily. Oral administration of metformin significantly (p < 0.05) reduced the clinical disease progression; however, we did not observe any delay in the disease onset (Fig. 1D). Metformin-treated animals did not have 100% EAE incidence. We calculated clinical score without nonresponsive mice and observed a significant difference (3.27 ± 0.48 vehicle-treated vs 2.35 ± 0.47 metformin-treated excluded nonresponsive mice; p < 0.05). The animals treated by the i.p. route (100 mg/kg) exhibited both delayed onset of disease and lower clinical disease scores (p < 0.05) with 100% disease incidence (Fig. 1E and Table I).

The anti-inflammatory effects of metformin on the induction of EAE led us to investigate whether initiation of therapy after onset of disease can induce any therapeutic effects. To address this hypothesis, metformin was administered to ongoing active EAE in SJL mice, starting on day 14 (when all of the mice had visible clinical symptoms of disease; 2.74 ± 0.27). Metformin at 100 mg/kg given once daily significantly decreased the clinical disease severity of EAE (Fig. 1F).

Metformin limits the infiltration of immune cells to the CNS

The hallmark of EAE disease is the infiltration of inflammatory cells into the CNS, leading to tissue damage (33). Therefore, we aimed to investigate the effect of metformin on the infiltration of inflammatory cells into the CNS of untreated and treated EAE animals. As shown in Fig. 2A, EAE, top panel, the untreated EAE mice showed profound infiltration of immune cells in the CNS. Treatment with metformin (100 mg/kg) significantly reduced the infiltration of these inflammatory cells into the CNS (Fig. 2A, EAE plus Met 100, lower panel). Nuclei are shown by Hoechst staining in Fig. 2B corresponding to the infiltration of immune cells in the CNS and the total counts of these nuclei are presented as bar graphs in Fig. 2C.

Metformin treatment inhibits inflammatory cytokines in the CNS

MS lesions are associated with expression of a wide range of proinflammatory cytokines (IFN-γ, TNF-α, IL-17, IL-1β, and IL-6) and their mediators (iNOS) (34, 35). To ascertain the status of these inflammatory cytokines in metformin-treated EAE mice, we examined the levels of mRNA in brain tissues from the metformin-treated and untreated EAE animals in chronically ill C57BL/6 mice at the peak of disease. We observed significantly higher levels of IFN-γ, TNF-α, IL-17, IL-1β, and IL-6 in the EAE animals in the CNS, whereas metformin-treated animals showed a marked decrease in the expression of these cytokines (Fig. 3, A–E). Furthermore, the expression of the inflammatory mediator iNOS in the CNS of EAE animals was down-regulated by the metformin treatment (Fig. 3F). Also, the CNS from metformin-treated EAE animals exhibited significantly less expression of MMP9 and chemokines (RANTES or CCL5) which play a critical role in the infiltration of immune cells during EAE disease progression (Fig. 3, G and H).

Metformin inhibits cell adhesion molecule (CAM) expression in the CNS of EAE-diseased animals

The selective entry of activated leukocytes into the CNS is regulated by specific interactions at the endothelial boundary (36, 37). Under inflammatory conditions encountered in the CNS in EAE/MS, activated endothelial cells up-regulate the expression of CAMs, including ICAM-1, VCAM-1, and E-selectin (38, 39). These CAMs interact with their ligands present on the leukocytes and aid in their infiltration. There are studies demonstrating that adhesion molecule expression precedes EAE clinical symptoms, suggesting a critical role of adhesion molecules in the initiation of CNS inflammation (38, 40). Thus, we investigated the effect of metformin on expression of CAMs (ICAM, VCAM, and E-selectin) in the CNS of EAE-treated and untreated animals. Quantitative RT-PCR analysis shows that CNS tissues from untreated EAE animals have significantly induced expression of CAMs compared with control mice (Fig. 4). Treatment with metformin markedly down-regulated the expression of these CAMs in the CNS of EAE-treated animals (Fig. 4, A–C).

Metformin restored lipid alterations in the CNS of EAE mice

One of the mechanisms of action of metformin has been shown to be via activation of AMPK (24, 26). Recently, we have investigated the status of AMPK during EAE disease progression and observed that the activity of AMPK is significantly down-regulated in the brain (41). To examine the effect of metformin on AMPK activity in brain, mice were killed at the peak of disease (day 16) and brains were processed for AMPK activity by immunoprecipitating AMPKα followed by a kinase assay using recombinant ACC as a substrate. As depicted in Fig. 5A, metformin treatment restored AMPK activity in total brain homogenates in treated EAE compared with vehicle-treated EAE mice. Decreased AMPK activity may lead to increased ACC and HMG-CoA reductase activities, which are the rate-limiting enzymes for fatty acid and cholesterol synthesis, respectively. Phosphorylation of
Metformin corrects AMPK activity and lipid alteration in brains of treated EAE animals. Active EAE was induced in the C57Bl/6 mice with MOG35–55 and treated with metformin (100 mg/kg). At day 16, total brain homogenate was processed for the AMPK assay (A) and for total lipid isolation (phospholipids (B), cholesterol (C), and FFA (D)). For the AMPK assay, 200 µg of protein was immunoprecipitated followed by kinase assay using recombinant ACC as a substrate (A). Densitometric values were plotted as bar graphs (n = 4). Data are means ± SD of the individual four values. * p < 0.05 and NS compared with control mice. $, p < 0.05 compared with EAE-untreated mice. Lipids were separated by TLC. Densitometry analysis of total phospholipids (PE, PI, PS, PC), cholesterol, and FFA was performed and plotted as a bar graph (n = 4; B–D). Data are means ± SD of the individual four values. *, p < 0.05 and NS compared with control mice. $, p < 0.05 compared with EAE-untreated mice.

**ACC and HMG-CoA reductase by metformin leads to inhibition of fatty acid and cholesterol biosynthesis.** Therefore, we examined the effect of metformin on neutral and phospholipids in the in brain during EAE from treated and untreated animals. We observed that total phospholipids and free fatty acids (FFA) were significantly increased in total brain homogenates during EAE disease without modulation of cholesterol levels which were restored by metformin treatment in treated animals (Fig. 5, B–D). These data suggest that metformin restores the activity of AMPK in brain, which gets down-regulated during disease condition, and thereby corrects lipids alteration in the CNS.

**Metformin mediated its anti-inflammatory effects via activation of AMPK in macrophages**

To examine the effect of metformin on AMPK activity, we treated the macrophage cell line RAW267.4 with various concentrations of metformin (1–10 mM). After 4 h of incubation, cells were processed for detection of the phospho-status of ACC using its specific Ab by immunoblot analysis. We observed that metformin induced the phosphorylation of ACC, which is a substrate of AMPKα, and indicates its intracellular activation (Fig. 6A, i and ii). Treatment with metformin also down-regulates the biosynthesis of phospholipids and neutral (cholesterol and FFA) lipids in RAW267.4 cells (Fig. 6B).

The expression of inflammatory mediators (iNOS and Cox2) has been implicated in various disease conditions. To determine the anti-inflammatory effect of metformin, we treated RAW267.4 cells with metformin (1–10 mM) for 2 h followed by stimulation with LPS (1 µg/ml) and the protein expression of iNOS and Cox2 was examined in cell lysates after 18 h of incubation with LPS using immunoblot analysis. Metformin treatment inhibited the LPS-induced expression of iNOS and Cox2 at 5 and 10 mM concentrations (Fig. 6C). To strengthen our hypothesis that the anti-inflammatory effects of metformin were mediated by activation of AMPK, we used another activator of AMPK, 5-aminooimidazole-4-carboxamide ribonucleoside (AICAR), which has been shown previously to be anti-inflammatory (28). As shown in Fig. 6C, AICAR also inhibited the induction of iNOS and Cox2 in these cells. To further establish the anti-inflammatory activity of metformin, we used primary macrophages isolated from spleens of C57Bl/6 mice and treated them with metformin followed by LPS.
(1 μg/ml) stimulation as described above. LPS induced production of NO and proinflammatory cytokines (TNF-α, IL-6, and IFN-γ) from macrophages that was significantly attenuated by metformin treatment in a dose-dependent manner (Fig. 6, D–G). Metformin also inhibited the expression of LPS (1 μg/ml)-, IFN-γ (50 U/ml)-, or IL-17 (50 ng/ml)-induced iNOS and Cox2 in macrophages (Fig. 6H, i–iii), suggesting that the anti-inflammatory action of metformin is not just confined to LPS signaling but also inhibits Th1- and Th17-mediated responses.

Metformin inhibits proliferation and production of proinflammatory cytokines in naïve CD3-positive T cells

Next, we examined the effect of metformin on naïve CD3-positive T cells. For this, naïve T cells were isolated from normal B6 mice and treated with various concentrations of metformin (1–10 mM) for 2 h followed by stimulation with plate-bound CD3/28 Abs. As depicted in Fig. 7A, metformin inhibits the T cell proliferation and production of proinflammatory cytokines IFN-γ (Th1) and IL-17 (Th17) (Fig. 7, B and C). These observations are further supported by the quantitative analysis of mRNA for Th1 or Th17 cytokines by RT-PCR. As shown in Fig. 7, D–G, metformin treatment inhibited expression of CD3/28-induced expression of IFN-γ and IL-17 along with their specific transcription factors T-bet and RORγT (Th17). These data suggest that metformin inhibits T cell proliferation, proinflammatory cytokines, and their specific transcription factors which may be one of the mechanisms through which metformin mediates its protection in EAE animals.

FIGURE 7. Metformin inhibits naïve T cell proliferation and Th1 and Th17 immune responses. The naïve CD3-positive T cells were isolated from B6 mice and stimulated with anti-CD3ε and anti-CD28 (1 μg/ml) for 24–72 h in the presence or absence of different concentrations of metformin (1–10 mM; A–G). For proliferation, the [³H]thymidine (1 μCi/well) was added at 48 h followed by an 18-h incubation and incorporation of thymidine was examined (A). The T cell supernatant was collected at 72 h and the level of Th1 (IFN-γ) and Th17 (IL-17) were detected by an OptEIA system (B and C). For detection of Th1 or Th17 cell-specific transcription factors T-bet or RORγT, naïve T cells were stimulated with CD3/28 as above and after 24 h of incubation, total RNA was isolated and processed for quantitative PCR to analyze the expression of IFN-γ, IL-17, T-bet, and RORγT (D–G). Data are representative of two independent experiments. ***, p < 0.001 as compared between unstimulated and CD3/28 stimulated and ***, p < 0.001 compared between CD3/28 stimulated and metformin treated.

FIGURE 8. Metformin (Met) inhibits Ag-specific T cell immune responses. Active EAE was induced in C57BL/6 mice with MOG35–55 as described in Materials and Methods. The mice in treated and untreated groups were killed at the peak of EAE disease and spleens cells were isolated and stimulated ex vivo with MOG35–55 (10 μg/ml) peptide for 48 h and then [³H]thymidine was added to the cells and incubated for an additional 18 h and incorporation of thymidine was measured (A). The culture supernatants of spleen cells were collected at 72 h and analyzed for inflammatory IFN-γ (Th1), IL-17 (Th17), IL-6, and anti-inflammatory IL-10 cytokines by an OptEIA system (B–E). Data are representative of two different experiments. ***, p < 0.001 compared between spleen cells from untreated EAE and treated mice.
Metformin inhibits recall responses and production of Th1 and Th17 cytokines in MOG-primed T cells

To examine the effect of metformin on Ag-specific immune responses in T cells, the mice were killed at the peak of EAE disease in untreated and treated groups. The spleen cells were stimulated ex vivo with MOG 35–55 peptide (10 μg/ml) and recall responses were measured by tritiated [3H]thymidine uptake and proinflammatory cytokines profile as described in Materials and Methods. The spleen cells from metformin-treated mice showed significantly reduced recall responses compared with untreated EAE animals when stimulated ex vivo with MOG peptide (Fig. 8A). To define whether the anti-inflammatory effects of metformin on EAE disease are associated with modulation of inflammatory cytokines, we analyzed the production of pro- and anti-inflammatory cytokines (IFN-γ, IL-17, IL-6, or IL-10) in the supernatant of spleens cells of metformin-treated and untreated EAE mice after ex vivo stimulation with MOG35–55 peptide. As shown in Fig. 8B–D, metformin reduced the production of inflammatory cytokines (IFN-γ, IL-17, and IL-6); however, the production of IL-10 (anti-inflammatory) was significantly up-regulated in spleen cells of treated mice (Fig. 8E). These data suggest that metformin possibly suppressed the encephalitogenic nature of T cells inhibiting the recall responses and production of inflammatory cytokines.

Discussion

Metformin was discovered in the 1920s in a search for guanidine-containing compounds with anti-diabetic activities and was introduced clinically in Europe in the 1950s. Since then it has a long history of human consumption; however, it was approved for diabetes in the United States in 1995 (42). Metformin is often the first drug used for newly diagnosed type 2 diabetic patients and in 2006 it accounted for 37% of the noninsulin diabetes prescriptions in the United States. A major action of metformin is suppression of hepatic glucose production (26). A minimal risk of hypoglycemia has been reported; however, it has some gastrointestinal side effects and very rarely causes lactic acidosis (43).

The present study is designed to investigate the prophylactic efficacy of metformin on the progression of an autoimmune inflammatory disease mediated by the infiltration of activated macrophages and T cells into the CNS. In this study, we used two different rodent models which partially mimic the relapsing-remitting (SIL) and chronic progressive (C57BL/6) form of MS. We observed that metformin was very effective in both models of EAE disease and exhibited anti-inflammatory effects on the CNS, macrophages, and T cells. Metformin exerted its immunosuppressive effect by inhibiting the expression of proinflammatory mediators (IFN-γ, TNF-α, IL-1β, IL-6, IL-17, iNOS, MMP9, and RANTES) and infiltration of immune cells, which was blocked by reducing the expression of CAMs (ICAM, VCAM, and E-selectin) on vascular cells. The observed inhibition of inflammatory cytokines in the CNS suggests that cells responsible for the production of these cytokines may be the direct target of metformin. Therefore, to examine this possibility, we used macrophages in vitro with inflammation induced by endotoxin (LPS). Metformin treatment blocked the production of NO and proinflammatory cytokines and expression of iNOS and Cox2 in macrophages, further supporting its anti-inflammatory action. These observations are in agreement with other reports where the anti-inflammatory effects of metformin have been documented (15, 44).

Metformin mediates its action by activating AMPK, which is a master sensor and regulator of energy homeostasis in mammalian cells and also a therapeutic target for metabolic disorders (45). AMPK activation affects many pathways, generally causing conservation and generation of ATP (46). Our data support this notion because metformin induced activation of AMPK in the brain of treated EAE mice and in macrophages and inhibited the expression of inflammatory cytokines and their mediators. It has been shown that another AMPK activator (AICAR) also inhibited the production of proinflammatory mediators (TNF-α, IL-1β, IL-6, and NO) in brain glial cells and in macrophages via inhibition of NF-κB and the C/EBP pathways (28) and attenuated LPS-induced inflammation in rats (28). Under recall response, we observed that metformin-treated mice exhibited inhibition in the production of proinflammatory cytokines and induction of IL-10 compared with vehicle-treated mice. A recent study suggested that AMPK acts as a potent counterregulator of inflammatory signaling pathways in macrophages since transfection of constitutively active AMPK in macrophages inhibited proinflammatory cytokines (TNF-α and IL-6) and, on the other hand, increased the production of an anti-inflammatory cytokine (IL-10) (47). The ability of AMPK to be rapidly activated by anti-inflammatory stimuli, or rapidly inactivated by proinflammatory stimuli, combined with the downstream consequences of AMPK activity that we observed herein, implicates AMPK as a “master regulator” of macrophage functional polarization. This study supports our finding published in 2004 (28), which indicates AMPK as an anti-inflammatory molecule.

Earlier it has been shown that AICAR attenuated EAE disease progression in mice by switching Th1 to Th2-type immune responses, suggesting that these molecules exert their anti-inflammatory effects on T cells (29). Metformin showed similar properties in T cells as it inhibited the recall responses and the production of inflammatory cytokines (IFN-γ, IL-17, and IL-6) in encephalitogenic T cells from treated EAE mice with increased production of IL-10. The role of IFN-γ (Th1)- or IL-17 (Th17)-producing cells is controversial in EAE disease since both of the cells have been shown to induce the disease (13, 48). Recently, it has been reported that Th1 cells induce EAE disease with the help of CD11b-positive macrophages; however, Th17 cells need Ly6G-positive neutrophils to exert similar effects (13, 48–51). Metformin inhibits the production of both Th1 and IL-17 cytokines in naïve T cells simulated with CD3/28 along with their associated transcription factors T-bet and RORγ, which primarily regulate the generation of these cytokines in Th1 or Th17 cells. Similarly, we observed inhibition of Th1 (IFN-γ) or Th17 (IL-17) in the CNS of metformin-treated EAE animals, suggesting the possible mechanism of its protective action.

Metformin inhibited the expression of adhesion molecules like ICAM, VCAM, and E-selectin and thereby reduced the infiltration of mononuclear cells into the CNS, as CAMs are directly involved in the transmigration of activated macrophages across the blood-brain barrier. These observations are in agreement with data published from two different clinical trials conducted in patients with impaired glucose tolerance and diabetes where metformin administration reduced the levels of soluble ICAM, VCAM, and E-selectin (52, 53). Inhibition of RANTES or CCL5 with metformin suggests that it limits the migration of T cells as these chemokines attract the activated T cells to the site of inflammation (54). Moreover, the mechanism of metformin is proposed to be via downregulation of the NF-κB pathway in endothelial cells (44), which is a prerequisite transcription factor for expression of CAMs (ICAM, VCAM, and E-selectin) (55–57). The mechanism of action of metformin seems to be similar to AICAR (58) since metformin also inhibits degradation of IkBα by inhibiting IkB kinase activity that results in suppression of cytokine-induced NF-κB activation in HUVECs (44).

There is no cure available for MS; however, a number of medications can be used to treat the disease symptomatically such as...
corticostereoids, IFN-β-1B (Betaseron), IFN-β (Avonex), and co-polymer I. Our study provides evidence that metformin has anti-inflammatory properties in vivo and in vitro, and most interestingly, it has good bioavailability and can be given orally which may reduce the cost of therapy, frequent doctor visits, and painful administration of drugs. Our work shows great implications for clinical research and offers the possibility of developing effective therapy alone or in combination with existing therapies for MS.

Acknowledgments
We thank Dr. Anne G. Gilg for critical reading of this manuscript and Joyce Bryan and Carrie Barnes for their technical assistance. We also acknowledge the generous support of Prof. Indjeri Singh for providing infrastructure for conducting this study.

Disclosures
The authors have no financial conflict of interest.
