IL-6 Is Required for Airway Mucus Production Induced by Inhaled Fungal Allergens

Wendy A. Neveu,* Jenna B. Allard,† Oliver Dienz,* Matthew J. Wargo,† Gennaro Ciliberto,‡ Laurie A. Whittaker,† and Mercedes Rincon2*†

Allergic asthma is caused by inhaled allergens and is characterized by airway eosinophilia, as well as mucus hypersecretion, which can lead to airflow obstruction. Despite the association of increased IL-6 levels with human atopic asthma, the contribution of IL-6 to the development of allergic airway inflammation triggered by inhaled allergens remains unclear. In this study, we examined the role of IL-6 in a mouse model of allergic airway inflammation induced by direct airway exposure to extracts of Aspergillus fumigatus, a common allergen in humans. We show that inhaled A. fumigatus extracts rapidly trigger the production of IL-6 in the airways. IL-6 appears to be dispensable for the recruitment of eosinophils to the lung during the development of allergic airway inflammation. However, IL-6 is essential for mucus hypersecretion by airway epithelial cells triggered in response to inhaled A. fumigatus Ags. Impaired mucus production caused by IL-6 deficiency correlates with a severe reduction in the levels of IL-13, a major inducer of mucin glycoproteins. Thus, IL-6 is a key regulator of specific hallmark features of allergic airway inflammation and it could be a potential target for pulmonary diseases that are associated with goblet cell metaplasia and mucus hypersecretion. The Journal of Immunology, 2009, 183: 1732–1738.

Interleukin-6 is a multifunctional cytokine that is produced by a variety of hematopoietic and nonhematopoietic cell types in response to diverse stimuli (1). Although IL-6 was originally considered a surrogate marker of inflammation, similar to IL-1β and TNF-α, recent studies have shown that IL-6 influences the effector functions of various CD4+ T cell subsets. IL-6 inhibits Th1 differentiation through the up-regulation of SOCS1 (2) and promotes Th2 differentiation by the induction of NFAT (3) and c-Maf (4) during early CD4+ T cell activation. In addition, IL-6 induces the differentiation of Th17 effector cells in the presence of TGFβ (5–7). In contrast, it inhibits regulatory T cell development, most likely by suppressing Foxp3 expression (6, 8, 9). Its role in promoting Th2 and Th17 differentiation, along with inhibiting regulatory T cell activity, suggests that IL-6 might play a role in the onset and/or progression of diseases that are associated with these types of immune responses. Allergic asthma is a chronic inflammatory disease of the airway that occurs in response to inhaled allergens such as ragweed pollen, cat dander, house dust mites, and fungi. The development of a CD4+ Th2 immune response and its associated cytokines (e.g., IL-4, IL-5, and IL-13) are known to play an important role in the pathogenesis of allergic asthma. IL-4 promotes IgE isotype switching in B cells to produce primarily IgE and IgG1 (10). IL-5 promotes eosinophil survival, differentiation, and migration (11), whereas IL-13 induces mucus metaplasia and airway hyperresponsiveness (12–14). Despite the role of Th17 cells in inflammation (15), the function of this subset and its signature cytokines IL-17A and IL-17F in allergic airway inflammation is less clear. IL-17R-deficient mice exhibit a decrease in eosinophil recruitment, Th2 cytokine production, and IgE levels during induction of allergic airway inflammation, suggesting that IL-17 is required during the initiation of allergic asthma (16, 17). However, exogenous administration of IL-17 during allergen challenge decreases local Th2 cytokine production and eosinophilia through repressing eotaxin production by lung epithelial cells (16).

Despite the role of IL-6 in Th2 and Th17 differentiation, its relative contribution to allergic airway inflammation remains unclear. Correlation studies in patients with asthma have shown increased IL-6 levels in bronchoalveolar lavage fluid (BALF) (18) and serum (19), as well as increased IL-6 production from cultured lung epithelial cells (20), suggesting a role for IL-6 in asthma pathogenesis. However, studies in mice have yielded conflicting results. Studies examining acute or chronic allergic airway inflammation induced by i.p. OVA immunization with alum followed by challenge with aerosolized OVA in IL-6 knockout (KO) mice show increased airway eosinophilia and Th2 cytokine production, suggesting that IL-6 may negatively regulate allergic airway inflammation (21, 22). In contrast, local disruption of IL-6 signaling in the lung by intranasal administration of an IL-6Ra-blocking Ab before OVA challenge decreases OVA-induced Th2 inflammation in vivo, suggesting that IL-6 positively regulates the Th2 immune response (23). Overall, whether IL-6 promotes or inhibits Th2 inflammation or even acts in a dual fashion in allergen-induced airway inflammation remains unclear.

In this study, we examined the role of IL-6 in allergic airway inflammation induced by repeated direct exposure of the lungs to extracts of Aspergillus fumigatus (A.f.), a common spore-forming fungi and known allergen in humans (24), without previous i.p.

immunization. We show that IL-6 is essential specifically for the development of mucus metaplasia in the airways in response to inhaled allergen, but it is dispensable for the recruitment of eosinophils to the lung. Thus, the elevation of IL-6 found in some respiratory diseases (e.g., chronic obstructive pulmonary disease and allergic asthma) could contribute to the pathogenesis of the disease by promoting mucus hypersecretion.

Materials and Methods

Mice

C57BL/6d mice were purchased from The Jackson Laboratory. IL-6-deficient mice (IL-6−/−) generated by deletion of exon I, II, and III have been previously described (25) and were obtained from Dr. G. Ciliberto (Istituto di Ricerche di Biologia Molecolare P. Angeletti, Rome, Italy). IL-21-deficient mice have been previously described (26). All mice were housed under sterile conditions at the animal care facility at the University of Vermont (Burlington, VT). All procedures performed on the mice were approved by the University of Vermont Institutional Animal Care and Use Committee. Mice were administered oropharyngeal (o.p.) 5 μg of A.f. extracts (5 × 105) 2 weeks as previously described (27). For quantification of early cytokine/chemokine production, BALF was collected 6 or 24 h after A.f. dose. For analysis of allergic airway inflammation, mice were administered A.f. extracts on days 0, 7, and 14. Mice were euthanized 48 h after the last challenge and tissue was processed for analysis.

IL-6 levels in serum were measured after 6 h of i.p. immunizations of wild-type mice with 25 μg of OVA (Sigma-Aldrich) and either 2.25 mg of alum (Thermo Scientific) or 15 μg or A.f. extracts.

BALF collection, cell count, and cell differential

Cold PBS (1 ml) was instilled into the lungs as previously described (27). Cells were centrifuged and counted on the Advia cell counter (Bayer). Cells (5 × 105) were cytospun and stained with hema-3 (Biochemical Sciences). Two hundred cells per high power field were counted and classified as macrophages, neutrophils, lymphocytes, or eosinophils by cell morphology and staining.

CD4+ T cell purification and activation

Spleenic CD4+ T cells from A.f.-exposed animals were negatively selected as previously described (3). Briefly, cells expressing CD8, CD11b, NK1.1, and MHC class II were depleted using specific mAbs (BD Pharmingen) and Ig-coated magnetic beads (Qiagen). Isolated CD4+ T cells (1 × 106) were activated with 5 μg/ml plate-bound anti-CD3 (2C11) and 1 μg/ml soluble anti-CD28 (BD Pharmingen) mAbs for 24 h.

Lung CD4+ T cells were purified from lung cell homogenates by sorting on a FACS-Aria (BD Biosciences) for CD4+ (CD4+ T cells) and CD1d tetramer (CD1d tetramer negative to discard NKT cells) expression. Cells were restimulated with A.f. extracts (5 μg/ml in the presence of APCs (T cell-depleted spleen cells) for 72 h.

Cytokine and Ig detection

Detection of IL-6 and cotixin in BALF was performed using the mouse IL-6 and cotixin Duoset according to manufacturer’s instructions (R&D Systems). Multiple cytokines and chemokines were detected in BALF by using the Mouse 25-plex Panel (Bio-Rad). Samples were analyzed using the Bio-Plex Manager Software (Bio-Rad). Detection of IL-13 (R&D Systems), IL-4, and IFN-γ (BD Pharmingen) in cell supernatants by ELISA was conducted as recommended by the manufacturer using the corresponding Abs. Serum from anesthetized mice was collected by right heart puncture. Total IgG1 and IgE levels were determined by ELISA using capture and detection Abs according to manufacturer’s instructions (BD Pharmingen).

Lung histology

Formalin-fixed, paraffin-embedded sections were prepared as previously described (28). Sections were stained for H&E and periodic acid-Schiff (PAS) according to routine procedures. Three investigators blinded to each experimental group scored airway inflammation and mucus production in the following way: 0, no inflammation or mucus production; 1, mild inflammation or mucus production; 2, moderate inflammation or mucus production; 3, severe inflammation or mucus production with majority of airways involved. Images were obtained using the Olympus BX50 light microscope with an Optronics Magnafire digital camera.

FIGURE 1. A.f. induces rapid IL-6 production in the airway and peripheral blood. A, Wild-type mice (n = 4) were o.p. administered A.f. extracts. IL-6 levels in the BALF were assessed at 0 and 6 h postexposure by ELISA. The results indicate the mean ± SEM (p < 0.05). B, Wild-type mice were o.p. administered A.f. extracts and 6 h later cytokine/chemokine levels in BALF were determined by Bio-Plex. C, Wild-type mice were i.p. administered OVA with alum (n = 5) or A.f. (n = 4) and 6 h later serum IL-6 levels were measured by ELISA (*, p < 0.05). Data are representative of two or three independent experiments. KC, keratinocyte-derived chemokine.

RNA analysis

Total RNA was extracted from whole lung tissue and CD4+ T cells by using the RNeasy kit (Qiagen) as recommended by the manufacturer. First-strand cDNA synthesis was performed as previously described (27). Quantitative PCR was performed on cDNA using Assay on Demand probe/primer sets for IL-5, IL-13, IL-17, IL-21, Muc5AC, 18S, and β2-microglobulin (Applied Biosystems). Gene amplification was performed on an ABIPrism 7700 instrument from Applied Biosystems. Expression of target genes in the lung and CD4+ T cells was normalized to 18S and β2-microglobulin levels, respectively. Relative values were determined by the comparative Ct method.

Statistical analysis

The data are presented as the mean ± SEM. The significance of differences between two groups was determined by the Mann-Whitney U test with GraphPad Prism (v. 5.0). For all analyses, p < 0.05 is considered statistically significant and anything greater than this value is not significant.

Results

IL-6 is rapidly produced in the lung in response to A. fumigatus exposure

Allergen exposure in human subjects leads to increased IL-6 levels in BALF and sputum (18, 29). Several studies have shown a role of IL-6 in the differentiation of CD4+ T cells into specific effector cell subsets. Thus, IL-6 produced in the lung upon allergen exposure could modulate the type of CD4+ T cell response that develops against inhaled Abs. Fungi (e.g., A. f. and A. alternata) are commonly encountered environmental allergens and act as asthma triggers (30). We have previously shown that direct lung exposure to A.f. extracts by o.p. administration in the absence of adjuvant is sufficient to induce allergic airway inflammation characterized by eosinophilia, mucus hypersecretion, and Th2 cytokine production (27). To determine whether A.f. exposure induces IL-6 production in the lung, IL-6 levels were examined in BALF from unexposed mice and mice treated o.p. with A.f. extracts. As early as 6 h postexposure, high levels of IL-6 were present in BALF, suggesting
that this cytokine could affect CD4+ T cell differentiation (Fig. 1A). We also examined the presence of other cytokines known to affect the differentiation of CD4+ T cells into specific effector Th cells. Although TNF-α and specific chemokines (e.g., KC and MIP-1α) were also induced (Fig. 1B), none of these is known to play a role in the polarization of T helper cells. Thus, direct A.f. exposure to the lung selectively triggered the production of IL-6 among the polarizing cytokines.

Although IL-6 is considered as an inflammatory cytokine that is induced early during the immune response by a number of adjuvants (31, 32), recent studies have shown that this cytokine could affect CD4+ T cell differentiation (Fig. 1A). We also examined the presence of other cytokines known to affect the differentiation of CD4+ T cells into specific effector Th cells. Although TNF-α and specific chemokines (e.g., KC and MIP-1α) were also induced (Fig. 1B), none of these is known to play a role in the polarization of T helper cells. Thus, direct A.f. exposure to the lung selectively triggered the production of IL-6 among the polarizing cytokines.

Serum IgG1 was analyzed for IL-4 and IL-6, and TGF-β interferes with eosinophil recruitment by inhibiting the production of eosinophilic airway inflammation leads to increased IL-17 production. We therefore examined whether A.f. extracts were restimulated ex vivo with Ag for 72 h. Lung CD4+ T cells from IL-6−/− mice were decreased compared with cells from wild-type mice (Fig. 3C). The levels of IFN-γ were also examined in these cells. Although very low, levels were comparable between IL-6−/− and wild-type cells (Fig. 3D). In addition, we purified lung-specific CD4+ T cells from A.f.-exposed wild-type and IL-6−/− mice and restimulated them ex vivo with Ag for 72 h. Lung CD4+ T cells from IL-6−/− mice also produce less IL-4 (Fig. 3E), but more IFN-γ (Fig. 3F), than CD4+ T cells from wild-type mice, further supporting the role of IL-6 in promoting Th2 while inhibiting Th1 CD4+ T cell differentiation.

Although the reduced production of IL-4 could explain the decreased IgG1 production, it could not account for the increased IgE levels observed in the IL-6−/− mice. Similar to IL-4, IL-21 induces plasma cell differentiation and regulates Ab production by promoting IgG1, IgG2b, and IgG3 isotype switching (42, 43). However, it negatively regulates IgE production (44–46) by inducing the Id2 gene expression in B cells (45). We have recently shown that IL-6 alone is a highly specific and effective inducer of IgG1 in naive and memory CD4+ T cells and it is required for promoting IgG1, IgG2b, and IgG3 isotype switching (42). Therefore, we examined whether IL-21 in naive and memory CD4+ T cells from A.f.-exposed wild-type and IL-6−/− mice were measured. IL-21 was expressed in CD4+ T cells from A.f.-exposed wild-type mice (Fig. 4A), but it was almost undetectable in CD4+ T cells from IL-6−/− mice (Fig. 4A). Thus, the effect of IL-6 deficiency on IgE production during A.f.-induced allergic airway inflammation is likely an indirect effect caused by insufficient IL-21 production from CD4+ T cells.

Increased IgE levels in A.f.-exposed IL-6−/− mice correlate with the requirement of IL-6 for IL-21 production

Because another hallmark feature of allergic airway inflammation is the production of the Ab isotypes IgE and IgG1 (37), we measured serum Ab levels from A.f.-exposed mice. IL-6−/− mice showed significantly lower circulating levels of IgG1 than wild-type mice in response to A.f. (Fig. 3A). However, serum IgE levels in A.f.-exposed IL-6−/− mice were elevated compared with the levels in exposed wild-type mice (Fig. 3B). IL-6 therefore contributes to IgG1 production during the induction of allergic airway inflammation, although it seems to have a negative effect on IgE production.

The Th2 cytokine IL-4 is a critical factor that drives Ab production in allergic airway inflammation because it promotes B cell Ig class switching to IgE. IgG1, and IgG2b (38, 39). Because IL-6 induces IL-4 production by CD4+ T cells (40, 41), we examined IL-4 levels in splenic CD4+ T cells isolated from A.f.-exposed wild-type and IL-6−/− mice upon ex vivo restimulation. Levels of IL-4 by CD4+ T cells from IL-6−/− mice were decreased compared with cells from wild-type mice (Fig. 3C). The levels of IFN-γ were also examined in these cells. Although very low, levels were comparable between IL-6−/− and wild-type cells (Fig. 3D). In addition, we purified lung-specific CD4+ T cells from A.f.-exposed wild-type and IL-6−/− mice and restimulated them ex vivo with Ag for 72 h. Lung CD4+ T cells from IL-6−/− mice also produce less IL-4 (Fig. 3E), but more IFN-γ (Fig. 3F), than CD4+ T cells from wild-type mice, further supporting the role of IL-6 in promoting Th2 while inhibiting Th1 CD4+ T cell differentiation.

Although the reduced production of IL-4 could explain the decreased IgG1 production, it could not account for the increased IgE levels observed in the IL-6−/− mice. Similar to IL-4, IL-21 induces plasma cell differentiation and regulates Ab production by promoting IgG1, IgG2b, and IgG3 isotype switching (42, 43). However, it negatively regulates IgE production (44–46) by inducing the Id2 gene expression in B cells (45). We have recently shown that IL-6 alone is a highly specific and effective inducer of IgG1 in naive and memory CD4+ T cells and it is required for IL-21 production in vivo (26). To test whether enhanced IgE levels in A.f.-exposed IL-6−/− mice were due to impaired IL-21 production, IL-21 levels in CD4+ T cells purified from A.f.-exposed wild-type and IL-6−/− mice were measured. IL-21 was expressed in CD4+ T cells from A.f.-exposed wild-type mice (Fig. 4A), but it was almost undetectable in CD4+ T cells from IL-6−/− mice (Fig. 4A). Thus, the effect of IL-6 deficiency on IgE production during A.f.-induced allergic airway inflammation is likely an indirect effect caused by insufficient IL-21 production from CD4+ T cells.

IL-21R-deficient mice have been shown to have increased baseline IgE levels due to the lack of IL-21 signaling (42). Similarly, analysis of serum IgE levels in unexposed IL-21−/− mice showed
IL-6 mediates mucus production by lung epithelium through the induction of IL-13 in CD4+ T cells in allergic airway inflammation. A–D, Wild-type (WT, n = 5) and IL-6−/− (n = 4) mice were exposed to A.f. extracts as described in Fig. 2. A, Mucus production in the lung was visualized by PAS staining of paraffin-embedded lung sections. Photomicrographs from A.f.-challenged wild-type (left) and IL-6−/− mice (right) are original magnification, ×200. B, Histological score indicating intensity of PAS staining for each group (p < 0.05). Muc5AC (p < 0.05; C) and IL-13 (p < 0.05; D) expression in the lung were determined by real-time RT-PCR and normalized to 18S RNA. E, Naive CD4+ T cells from wild-type mice were activated in vitro with anti-CD3 and anti-CD28 Abs in the presence or absence of IL-6 (100 ng/ml) or IL-4 (1 × 103 U/ml). IL-13 was measured in the culture supernatant after 48 h by ELISA in triplicate. *, p < 0.05 CD4+ T cells treated with IL-6 compared with cells activated in the presence of medium alone or IL-4.

Increased baseline IgE levels (Fig. 4B). To determine whether IL-6 deficiency could also lead to increased IgE secretion, we examined the basal levels of IgE in IL-6−/− mice. Similar to IL-21−/− mice, the IgE levels were significantly elevated in naive IL-6−/− mice (Fig. 4B). Together, these data indicate that both IL-21 and IL-6 deficiency result in systemic IgE hypersecretion and thereby increased IgE levels during allergic airway inflammation.

IL-6 is essential for mucus production by lung epithelial cells

A major feature of allergic airways disease is mucus metaplasia and mucus hypersecretion by airway epithelium. Excessive mucus production can lead to physical obstruction of smaller caliber airways (46). Goblet cell hyperplasia and increased mucus production require the adaptive immune response. Although mucus hypersecretion and eosinophilia in the lung are normally associated, they are two independent pathological events. We therefore examined the role of IL-6 in mucus production in the airway during allergic airway inflammation. Lung sections from A.f.-exposed wild-type and IL-6−/− mice were stained for PAS to visualize mucus production by airway epithelial cells. The PAS score was based on the intensity of PAS staining per airway and the total number of positive airways. Both the number of airways with mucus-producing cells and the number of mucus-producing cells per airway were strongly reduced in IL-6−/− mice compared with wild-type mice (Fig. 5, A and B), indicating that IL-6−/− mice were more resistant to developing mucus metaplasia. The impaired mucus production was further confirmed by examining the expression of the mucus glycoprotein Muc5AC in the lung by real-time RT-PCR. High levels of Muc5AC were present in A.f.-exposed wild-type mice whereas only marginal Muc5AC levels were detected in IL-6−/− mice (Fig. 5C). Thus, IL-6 is essential for mucus production in the airway.

Because IL-13 is the major cytokine involved in mucus production by lung epithelial cells (12, 13, 47), we investigated the effect of IL-6 deficiency on IL-13 expression during allergic airway inflammation. Correlating with the inability to produce mucus in the airway, a profound reduction in IL-13 expression in the lung was observed in IL-6−/− mice relative to wild-type mice (Fig. 5D). IL-13 is a Th2 type of cytokine that is primarily induced by IL-4 (48). To determine whether IL-6 could also directly promote IL-13 production by CD4+ T cells, naive CD4+ T cells were activated in vitro with anti-CD3 and anti-CD28 mAbs in the presence or absence of IL-6 or IL-4. IL-13 in the culture supernatant was measured after 48 h. CD4+ T cells activated in the absence of exogenous cytokine produced marginal levels of IL-13. IL-4 had a minimal effect on IL-13 levels at this time of activation (Fig. 5E). In contrast, IL-6 strongly up-regulated IL-13 production (Fig. 5E). Thus, IL-6 directly induces IL-13 production by CD4+ T cells during activation, providing a potential mechanism by which IL-6 enhances mucus production in the airways following allergen exposure.

Discussion

Although IL-6 has been shown to be elevated in allergic asthma in humans, its exact contribution to the hallmark features of this disease remains unclear. Correlative studies have provided evidence that IL-6 is up-regulated in the airway and systemic circulation of asthmatic patients (18, 19, 49–53). However, the traditional view of IL-6 as a proinflammatory biomarker together with TNF-α and IL-1β suggests that increased IL-6 levels in asthma could merely be a result of an ongoing inflammatory response, rather than serving a functional role. Recently, we have shown that there is a selective increase in IL-6, but not TNF-α and IL-1β, in the large central airways of mildly allergic asthmatic patients compared with healthy control subjects (W. A. Neveu, J. Allard, D. Raymond, L. Bourassa, S. Burns, J. Bunn, C. Irvin, D. Kaminsky, M. Rincon, submitted for publication). This increase in IL-6 inversely associates with airflow obstruction. Similar observations were made in a patient cohort that included asthmatics with more severe disease (54). Together, these data suggest that IL-6 influences pathological changes within the airway that results in increased airflow resistance. In this study, using null IL-6−/− mice, we show for the first time that indeed IL-6 is essential for mucus production during allergic airway inflammation.

Increased mucus production from lung epithelium in chronic inflammatory diseases such as asthma can physically obstruct the airway, resulting in an increase in airflow resistance (46, 55). The lung uses a homeostatic mechanism that balances mucous production with airway clearance (56). However, if either of these components are perturbed, it can lead to lung dysfunction. Thus, the presence of IL-6 in the asthmatic airway could contribute to lung function through induction of mucus hypersecretion. The effect of IL-6 on mucus production may be a consequence of IL-13 expression in the lung and IL-13 inducing mucus cell metaplasia in the airway. Alternatively, because in vitro studies have shown that IL-6 can directly induce the mucin genes Muc5AC and Muc5B in human lung epithelial cell lines, we cannot exclude the possibility that IL-6 may have a direct effect on mucus production by lung epithelial cells during allergic airway inflammation (57).

The role of IL-6 in the development of allergen-induced airway eosinophilia remains unclear. In vivo blockade of IL-6 signaling by the administration of an anti-IL-6R Ab during the challenge phase with the OVA Ag seems to decrease the accumulation of
caused by insufficient IL-21 production by CD4 cells. In our study, we used IL-6−/− mice that were previously generated by deletion of Exons I, II, and III of the IL-6 gene (25). The IL-6 KO mice used in the previous studies were generated by insertion of the neomycin-resistance cassette in Exon 2 in the same orientation as the IL-6 gene (58), leading to increased levels of IL-6 mRNA that may encode for a potential IL-6. We also examined the response to IL-6 exposure in those IL-6 KO mice and found a significantly higher number of eosinophils in the airway in these mice than in wild-type mice (data not shown), corroborating the observations that were previously published using the OVA model (21, 22). Thus, the apparent difference in the two studies is likely due to the difference in the genetically manipulated mouse models used to disrupt IL-6 gene expression.

In this paper, we describe for the first time that IL-6 deficiency leads to hyper-IgE production, and it is more pronounced upon induction of allergic airway inflammation. This phenotype resembles that of mice deficient for IL-21. Considering the suppressive effect of IL-21 on IgE production, partly mediated by Id2 activity (45), and the selective induction of IL-21 expression by IL-6 (59), we propose that increased IgE production in IL-6−/− mice is indirect due to the differences in the genetically manipulated mouse models used to disrupt IL-6 gene expression.

Acknowledgments

We thank Kieren Marr (Fred Hutchinson Cancer Center, University of Washington, Seattle, WA) for providing us with the A.f. extracts. We thank Timothy Hunter and Mary Lou Shane (DNA Sequencing Facility, University of Vermont, Burlington, VT) for assistance with real-time RT-PCR analysis and Colette Charland for cell sorting. We also thank Charlie Irvin, Elizabeth Bonney, Janice Bunn, and Juan Anguita for helpful discussion.
