Leukotriene B<sub>4</sub> Mediates Neutrophil Migration Induced by Heme

Ana Paula T. Monteiro,*1 Carla S. Pinheiro,*1 Tatiana Luna-Gomes,* Liliane R. Alves,† Clarissa M. Maya-Monteiro, § Barbara N. Porto, ‡ Christina Barja-Fidalgo, †† Claudia F. Benjamim,*,† Marc Peters-Golden, †† Christianne Bandeira-Melo,* Marcelo T. Bozza, ‡ and Claudio Canetti* 2

High concentrations of free heme found during hemolytic events or cell damage leads to inflammation, characterized by neutrophil recruitment and production of reactive oxygen species, through mechanisms not yet elucidated. In this study, we provide evidence that heme-induced neutrophilic inflammation depends on endogenous activity of the macrophage-derived lipid mediator leukotriene B<sub>4</sub> (LTB<sub>4</sub>). In vivo, heme-induced neutrophil recruitment into the peritoneal cavity of mice was attenuated by pretreatment with 5-lipoxygenase (5-LO) inhibitors and leukotriene B<sub>4</sub> receptor 1 (BLT1) receptor antagonists as well as in 5-LO knockout (5-LO<sup>−/−</sup>) mice. Heme administration in vivo increased peritoneal levels of LTB<sub>4</sub> prior to and during neutrophil recruitment. Evidence that LTB<sub>4</sub> was synthesized by resident macrophages, but not mast cells, included the following: 1) immunolocalization of heme-induced LTB<sub>4</sub> was compartmentalized exclusively within lipid bodies of resident macrophages; 2) an increase in the macrophage population enhanced heme-induced neutrophil migration; 3) depletion of resident mast cells did not affect heme-induced LTB<sub>4</sub> production or neutrophil influx; 4) increased levels of LTB<sub>4</sub> were found in heme-stimulated peritoneal cavities displaying increased macrophage numbers; and 5) in vitro, heme was able to activate directly macrophages to synthesize LTB<sub>4</sub>. Our findings uncover a crucial role of LTB<sub>4</sub> in neutrophil migration induced by heme and suggest that beneficial therapeutic outcomes could be achieved by targeting the 5-LO pathway in the treatment of inflammation associated with hemolytic processes. The Journal of Immunology, 2011, 186: 6562–6567.

Inflammation has emerged as an essential component of pathophysiologic situations in which increased hemolysis can lead to high levels of free heme, such as in malaria (1), sickle cell disease (SCD) (2), the hemolysis, elevated liver enzyme levels, and low platelet count syndrome (3), and regional turbulent blood flow (4). SCD is associated with inflammatory stresses within the microcirculation, such as leukocytosis, elevated levels of inflammatory cytokines, and activation of neutrophils, monocytes, and endothelial cells (5–8). The heme molecule serves as the functional component of a wide variety of crucial proteins and is involved in various cellular processes such as gene transcription/translation, cell differentiation, and proliferation (9–13). Heme is therefore of fundamental importance for life. However, heme is also inherently dangerous, particularly when it escapes from intracellular sites. Free heme has several proinflammatory activities, including induction of cytokines and acute-phase proteins, as well as the ability to induce neutrophil migration and activation (14, 15). Heme oxygenase (HO) is a family of ubiquitous enzymes that catalyze the degradation of heme to bilirubin, producing equimolar amounts of biliverdin, free iron, and carbon monoxide. There are three known HO isoforms: the inducible isoform HO-1 and the constitutive isoforms HO-2 and HO-3. The expression of inducible HO-1 is positively modulated by a number of inflammatory mediators, by oxidative stress, and also by heme itself (16). Neutrophil migration into tissues is the hallmark of numerous acute inflammatory reactions and represents a highly regulated multistep process that is controlled by a variety of inflammatory mediators, including leukotriene (LT) B<sub>4</sub>.

LTB<sub>4</sub> is a lipid mediator derived from the 5-lipoxygenase (5-LO) pathway of arachidonic acid metabolism. 5-LO, in conjunction with 5-LO activating protein, oxygenates arachidonic acid to form LT A<sub>4</sub>. Hydrolysis of this intermediate forms LTB<sub>4</sub>, a potent leukocyte chemoattractant that also displays leukocyte activating functions (17). Regarding hemolysis-related inflammatory conditions, it has been shown that increased LT concentrations are found in plasma and urine of SCD patients at steady state (18, 19), and that plasma levels of LTB<sub>4</sub> are further increased during vaso-occlusion and acute chest syndrome episodes (20).

In the current study, a potential role of the 5-LO product LTB<sub>4</sub> in heme-induced neutrophil migration was investigated. In addition, we tested the hypothesis that macrophages are the cells involved in generating LTB<sub>4</sub> in response to heme stimulation. Our findings indicate that heme-elicited neutrophil recruitment is mediated by...
macrophage-derived LTB₄, whose intracellular synthesis is compartmentalized within cytoplasmic lipid bodies.

Materials and Methods

Animals
C57BL/6, SV129, or 5-LO-deficient (129-Alox5tm1Fun, 5-LO⁻/⁻) mice weighing 20–22 g were used. 5-LO mice were bred in the unit for transgenic animals at Bio-Rio (Federal University of Rio de Janeiro, Rio de Janeiro, Brazil) from breeders obtained from The Jackson Laboratory (Bar Harbor, ME). C57BL/6 mice were obtained from Instituto Oswaldo Cruz (Rio de Janeiro, Brazil). The animals were housed in temperature-controlled rooms and received water and food ad libitum until used. All experiments were conducted in accordance with National Institutes of Health guidelines on the welfare of experimental animals.

Materials
Heme was purchased from Porphyrin Products (Logan, UT) and LTB₄ from Cayman Chemical (Ann Arbor, MI). Zileuton [N-(1-benzo[b]thien-2-yl)ethyl]-N-hydroxyurea] was obtained from Ono Pharmaceutical (Osaka, Japan). AA861 was purchased from Biomol Research Laboratories (Plymouth Meeting, PA). LY 292476 was obtained from Eli Lilly (Indianapolis, IN). CP 105,696 was a gift from Dr. Henry Showell (Pfizer Laboratories, Groton, CT). Thioglycolate (3% w/v, 1 ml i.p.) was injected in a group of animals, and as indicated in the figure legends of this article. Statistical significance was set at p < 0.05.

Cell culture
To determine whether peritoneal macrophages release neutrophil chemoattract activity after heme stimulation, peritoneal cells were harvested and cultured in 24-well plates for 1 h at 37°C in an atmosphere of air with 5% CO₂. The plates were then washed three times with RPMI 1640 to remove the nonadherent cells. The adherent cells were incubated for 30 min at 37°C in fresh medium (control) or in medium containing heme (3, 10, or 30 nmol well⁻¹). Subsequently, the supernatants were discarded, and after three further washes the cells were incubated for 6 h with 0.3 ml RPMI 1640 alone. After this incubation period, the supernatants were collected and stored at −70°C for LTB₄ determination. Cell-free peritoneal lavage fluids obtained after i.p. challenge with heme (50 nmol in 0.5 ml saline) or saline alone (control) were also collected and frozen (−70°C) until LTB₄ determination.

EicosaCell for immunodetection of intracellular, newly formed LTB₄ within peritoneal leukocytes

LTB₄ immunodetection at its subcellular sites of synthesis within leukocytes was performed as previously described (21). In brief, leukocytes were recovered from peritoneal cavities 2 h after heme or sterile saline injection by washing the cavity with 500 μl HBSS and immediately mixing with 500 μl water-soluble 1-ethyl-3-(3-dimethylamino-propyl) carbodiimide (EDAC in HBSS, 0.5% final concentration with cells) (Sigma), used to cross-link eicosanoid carbboxyl groups to amines in adjacent proteins. After 15 min incubation at 37°C with EDAC to promote cell fixation and permeabilization, peritoneal leukocytes were then washed with HBSS, cytopsium onto glass slides, and blocked with HBSS containing 1% BSA for 30 min. The cells were then incubated overnight with anti-LTB₄ Ab (Cayman Chemical) or irrelevant IgG overnight and the anti-adipose-differentiation-related protein (anti-ADR-P, 1:300 final dilution) to distinguish cytoplasmic lipid bodies within leukocytes. The cells were washed with HBSS for 10 min (three times) and incubated with Alexa 488-labeled anti-rabbit IgG (1:1000 final dilution) plus Alexa 546-labeled anti-guinea pig (1:1000 final dilution) secondary Abs for 1 h.

The specificity of the LTB₄ immunolabeling was demonstrated by 1) lack of immunoreactivity within leukocytes recovered from heme-injected animals that were incubated with irrelevant IgG (data not shown); 2) lack of LTB₄ immunolabeling within resident leukocytes recovered from saline-injected animals that were incubated with anti-LTB₄ Ab; and 3) lack of LTB₄ immunolabeling within resident leukocytes recovered from heme-injected animals that were treated with the 5-LO inhibitor zileuton (60 μg cavity⁻¹, i.p.) 1 h before peritoneal cell recovery. With 500 μl HBSS containing 25 μM zileuton and then incubated with anti-LTB₄ Ab.

The images were obtained using a Olympus BX51 fluorescence microscope equipped with a Plan Apo ×100 1.4 Ph3 objective and an Olympus 72 digital camera (Olympus Optical, Japan) in conjunction with Cell Imaging Software for Life Science Microscopy (Olympus Life Science Europa, Germany). The images were edited using Adobe Photoshop 5.5 software (Adobe Systems, San Jose, CA).

Results
Heme-induced in vivo neutrophil migration depends on newly synthesized LTB₄ acting on BLT₁ receptors
It has been previously shown that the intrathoracic administration of heme induces a dose-dependent neutrophil accumulation in rat pleural cavities (15). However, the mechanisms by which heme induced neutrophil recruitment were not characterized. Because LTB₄ is a well-characterized chemotaxant of neutrophils (22, 23) and has been implicated in neutrophil migration induced by several inflammatory mediators, such as TNF-α (24), IL-1β (25), IL-18 (26), MIP-1α (27), and MIP-2 (28), we hypothesized LTB₄ to be a mediator of heme-induced neutrophil migration. Such involvement of LTB₄ was confirmed by using two completely distinct experimental approaches. First, WT or 5-LO⁻/⁻ mice were

Downloaded from http://www.jimmunol.org/ by guest on April 22, 2017
injected i.p. with heme (50 nmol) or saline, and neutrophil accumulation in the peritoneal cavity was evaluated 4 h later. As expected, heme administration was effective in triggering significant neutrophil recruitment to the peritoneal cavity in WT mice when compared with saline-injected mice (control). However, heme-induced neutrophil migration was clearly reduced in 5-LO−/− mice compared with that in heme-injected WT mice (Fig. 1A). Additionally, the migration induced by heme injection was also significantly inhibited in mice (WT, C57BL/6 mice) pretreated with the 5-LO inhibitors zileuton (Fig. 1B) and AA861 (not shown).

A variety of bioactive products generated via the 5-LO pathway are candidates for mediating this neutrophil recruitment. Fig. 1C implicates heme-driven LTB4 as a mediator of neutrophil migration via activation of BLT1 receptors, as in mice pretreated with two structurally unrelated BLT1 receptor antagonists, CP 105,696 and LY 292476 (Fig. 1C), heme-induced peritoneal neutrophilia was significantly reduced.

In vivo heme-elicted LTB4 synthesis takes place within newly assembled lipid bodies of resident peritoneal macrophages

In agreement with a role for endogenous LTB4 in vivo stimulation with heme elicited rapid synthesis/release of LTB4, which preceded heme-induced neutrophil migration. As shown in Fig. 2, peritoneal lavage fluid recovered 2 h after heme injection contained higher levels of LTB4 than after saline injection.

The cellular source of LTB4 synthesized during heme-driven inflammation was investigated by the direct intracellular immunofluorescence detection of newly formed LTB4 within resident macrophages. EicosaCell—a methodology that cross-links and immunolabels LTB4 at its sites of synthesis—resident macrophages were identified as the cell population responsible for LTB4 production during heme-induced inflammatory reaction (Fig. 3, top panel). As illustrated in the images of immunolabeled ADRP (Fig. 3) and enumerated in osmium-stained cells (data not shown), besides LTB4 synthesis, heme administration was also able to trigger rapid (2 h) assembly of new lipid bodies within resident peritoneal macrophages. The parallel between increased numbers of lipid bodies and levels of secreted LTB4 observed in heme-induced peritoneal macrophages appeared to reflect a functional correlation, as lipid body localization of newly formed LTB4 within macrophages was ascertained by colocalization with ADRP (Fig. 3). Supporting the specificity of LTB4 immunostaining within cytoplasmic lipid bodies of heme-stimulated peritoneal macrophages, virtually no immunofluorescent staining for LTB4 was localized within peritoneal macrophages of saline-injected mice (Fig. 3, inset panels) or 5-LO inhibitor-treated heme-stimulated mice (Fig. 3, bottom panels). Therefore, the presence of heme within the peritoneal compartment induces activation of resident macrophages with rapid formation of distinctive lipid bodies endowed with the enzymatic machinery necessary for LTB4 synthesis.

**FIGURE 1.** Heme-induced neutrophil migration in vivo depends on LTB4/BLT1. A, WT (sv129) or 5-LO−/− mice were injected i.p. with 50 nmol heme in 0.5 ml saline or saline alone (control). B. C57BL/6 mice were treated with saline (−; i.v.; 20 min before) or zileuton (3 mg kg−1; i.v.; 20 min before) and then challenged with heme (50 nmol in 0.5 ml saline) or saline alone (control). C, C57BL/6 mice were injected with saline (−; s.c.; 30 min before) or CP 105,696 (CP; 3 mg kg−1; s.c.; 30 min before) or LY 292476 (LY; 2 mg kg−1; s.c.; 30 min before) and administered heme (50 nmol) or saline (control). Mice were sacrificed 4 h later, peritoneal cavity cells harvested, and neutrophil migration was determined. Data are presented as the mean ± SEM. The results are of one experiment representative of three independent experiments performed with six mice per group. *p < 0.05 (compared with respective control), #p < 0.05 (compared with heme group in WT mice).

**FIGURE 2.** Heme-induced LTB4 production in vivo. Concentration of LTB4 in the peritoneal lavage fluids obtained 2 h after i.p. challenge with heme (50 nmol in 0.5 ml saline) or saline alone (control) was determined by EIA. Results are mean ± SEM; one experiment representative of three separate experiments performed with six mice per group. *p < 0.05 (compared with control group by Student t test).

**FIGURE 3.** Heme elicits LTB4 synthesis within cytoplasmic lipid bodies of peritoneal macrophages. EicosaCell analysis of LTB4 synthesis was performed 2 h after heme administration. An anti-LTB4 field was merged with an identical anti-ADRP field of fluorescent images of macrophages recovered from mice stimulated with saline (inset panel), heme (top panels), or heme plus zileuton treatment (bottom panels). Images show LTB4 immunoreactive lipid bodies (as identified by anti-ADRP) of heme-stimulated peritoneal macrophages. Image is representative of three separate experiments with three mice per group. Scale bars, 5 μm.
Macrophages, but not mast cells, participate in heme-induced neutrophil migration by generating LTB₄

Besides macrophages, resident peritoneal mast cells could represent an additional cellular source of LTB₄ involved in heme-induced neutrophil migration. To assess the differential contributions of these two cell populations in heme-induced peritoneal neutrophilia, the macrophage population was enhanced by thioglycolate administration, and functional mast cell numbers were depleted by chronic treatment with the mast cell degranulator compound 48/80. As observed in Fig. 4A (left panel), thioglycolate injection resulted in an increase in the peritoneal macrophage population after 72 h, as expected. The administration of heme in the peritoneal cavity of mice 72 h after pretreatment with thioglycolate caused a marked enhancement of neutrophil migration (Fig. 4A, right panel). In contrast, depletion of functional peritoneal mast cells by chronic 48/80 treatment (Fig. 4B, left panel) or by distilled water injection (data not shown) did not abrogate heme-induced neutrophil accumulation (Fig. 4B, right panel). Supporting the conclusion that macrophages play a central role in heme-induced neutrophil migration by producing LTB₄, we demonstrated that challenging thioglycolate-treated macrophage-enriched mice with heme resulted in an enhanced LTB₄ production compared with that observed in saline-treated animals injected with heme (Fig. 5A). Furthermore, mast cell depletion with compound 48/80 had no effect on LTB₄ production in vivo after saline or heme administration into the peritoneal cavity (Fig. 5B), reinforcing that mast cells are not involved in heme-induced neutrophil migration. Moreover, the same observation was also noted in H₂O-treated mice (data not shown). Together, these data suggest that resident macrophages, but not mast cells, control heme-evoked LTB₄-mediated neutrophil influx.

Heme-induced LTB₄ production in vitro

To evaluate whether heme is able to trigger LTB₄ synthesis within macrophages by a direct effect on these cells, we stimulated purified mouse peritoneal macrophages with heme in vitro. As shown in Fig. 6, peritoneal macrophages synthesize/release LTB₄ in a dose-dependent manner in response to in vitro heme stimulation, indicating that free heme directly triggers macrophage activation characterized by LTB₄ synthesizing activity.

Supernatant chemotactic activity from heme-stimulated macrophages is due to the presence of LTB₄

As can be observed in Fig. 7, the instillation of supernatants obtained from heme-stimulated macrophages induced neutrophil recruitment into the peritoneal cavity of naive mice, which mimicked the neutrophil migration induced by heme administration itself. In contrast, the i.p. injection of supernatants recovered from nonstimulated macrophages did not induce neutrophil accumulation. To evaluate if heme-stimulated macrophage supernatant chemotactic activity was a consequence of the presence of
LTB₄, we first evaluated the effect of a 5-LO inhibitor on its release. As shown in Fig. 7A, macrophage treatment with AA861 (5-LO inhibitor) was able to inhibit the release of the neutrophil chemotactic factor by heme-stimulated macrophages. Furthermore, injection of heme-stimulated macrophage supernatant failed to elicit neutrophil migration in mice pretreated with a BLT1 receptor antagonist (CP 105,696; Fig. 7B). Together, these data point to an essential role for macrophage-derived LTB₄ acting via the high-affinity receptor, BLT1, to induce neutrophil migration.

Discussion

Tissue injury after hemolytic episodes is associated with intense neutrophil accumulation. In pathological states such as SCD, high levels of free heme up to 20 μM have been observed (29). Many studies have demonstrated that neutrophil activation is present in patients with SCD (30–34). In this regard, it has been previously shown that heme causes neutrophil migration in vivo and in vitro as well as reactive oxygen species formation (15), but the mechanisms involved in this activation phenomenon are not fully understood. Data presented in this study demonstrate that heme-induced neutrophil migration and activation are LTB₄ dependent. In addition, the results also point to a central role for resident macrophages as the major LTB₄ source.

Heme-induced neutrophil migration into the peritoneal cavity of mice depends on the LTB₄/BLT1 axis, as pretreatment of the animals with 5-LO inhibitors (zileuton and AA861) or BLT1 receptor antagonists (CP 105,696 and LY 292476) inhibited neutrophil accumulation. Further confirmation was obtained with the use of 5-LO--/– mice, in which neutrophil recruitment in response to heme challenge was also attenuated. Both macrophages and neutrophils are recognized to have a robust capacity for LTB₄ synthesis, and generation of this activating lipid was triggered by heme in both cell types. Data in the literature support a role for LTs in SCD pathophysiology, in which urinary and plasma levels have been proposed as potential biomarkers (19, 35). To assess the involvement of LTB₄ in heme-induced neutrophil recruitment, we determined its production in vivo. As presented in Fig. 2, LTB₄ production after i.p. heme challenge was 3-fold higher than that in the control group. The idea that LTs contribute to SCD pathophysiology is reinforced by the recent finding that 5-LO and 5-LO activating protein, key LT biosynthetic proteins, were significantly increased in PBMCs obtained from patients with SCD compared with controls (36).

Mast cells and macrophages are resident cells implicated in recruiting neutrophils and eosinophils through the release of chemotactic factors (37–39). It has been demonstrated that manipulating the numbers of these cell types alters neutrophil recruitment induced by several inflammatory mediators, such as TNF-α, LTB₄, IL-8, and CCL2 (MCP-1) (36, 37, 40). Thus, we evaluated the effects on neutrophil migration induced by heme administration of enhancing the macrophage population and depleting the mast cell population. We found that heme-induced neutrophil migration was dependent on resident macrophages, but not on mast cells. Corroborating the central position of macrophages in neutrophil recruitment induced by heme, we noted a marked enhancement of heme-induced LTB₄ production when the macrophage population was increased. Ex vivo peritoneal macrophage stimulation with heme also induced LTB₄ production in a dose-response manner, confirming the in vivo observations. Neutrophil chemotactic activity was also noted in supernatants from heme-stimulated macrophages. Although our data implicate LTB₄ as a major mediator of heme-induced neutrophil migration, they do not rule out the possible participation of other mediators, such as cytokines and chemokines. In fact, it was demonstrated that murine macrophages release CXC chemokine KC and TNF-α when stimulated with heme (41). Nevertheless several inflammatory cytokines (TNF-α, IL-1β, IL-18, MIP-1α, and MIP-2) induce neutrophil migration in vivo by indirect mechanisms, dependent on 5-LO/LTB₄ pathway, demonstrating a close cross-talk between cytokines/chemokines and LTB₄, a fact not very often appreciated. The possible interplay between LTB₄ and other mediators in inflammatory responses to heme requires further investigation.

It is increasingly recognized that lipid bodies (or lipid droplets) are specialized sites involved in compartmentalization and amplification of eicosanoid synthesis. Lipid bodies are virtually absent in non-adipocytic cells, but increased numbers of these organelles have been described in inflammatory and cancer cells both in experimental models and in clinical conditions (42, 43).

To investigate the site of LTB₄ production within macrophages, heme was injected, and 2 h later the cells were harvested, and the
intracellular newly formed LTB₄ was immunodetected by the EicosaCell technique. LTB₄ was detected in a clear punctate pattern in the cytoplasm, near but separate from the nucleus, fully consistent in size and form with macrophage lipid bodies. Heme injection also induced lipid body formation (genesis), observed in Fig. 3 and also in osmium-stained cells (data not shown), which was absent or much less apparent in cells recovered from saline-injected mice. The relevance of lipid bodies as a site of LTB₄ formation in human neutrophils stimulated with heme remains to be determined.

To conclude our data, allow us to speculate that the inhibition of the synthesis or the actions of LTB₄ at BLT1 could be beneficial as a strategy to dampen inflammatory responses during pathological circumstances in which free heme is observed.
