ATP-Binding Cassette Transporter G1 Intrinsically Regulates Invariant NKT Cell Development

Duygu Sag,* Gerhard Wingender, † Heba Nowyhed,* Runpei Wu,* Abraham K. Gebre, ‡ John S. Parks, ‡ Mitchell Kronenberg, † and Catherine C. Hedrick*

ATP-binding cassette transporter G1 (ABCG1) plays a role in the intracellular transport of cholesterol. Invariant NKT (iNKT) cells are a subpopulation of T lymphocytes that recognize glycolipid Ags. In this study, we demonstrate that ABCG1 regulates iNKT cell development and functions in a cell-intrinsic manner. Abcg1<sup>−/−</sup> mice displayed reduced frequencies of iNKT cells in thymus and periphery. Thymic iNKT cells deficient in ABCG1 had reduced membrane lipid raft content, and showed impaired proliferation and defective maturation during the early stages of development. Moreover, we found that Abcg1<sup>−/−</sup> mice possess a higher frequency of V<sub>b</sub>8<sup>+</sup> iNKT cells, suggesting alterations in iNKT cell thymic selection. Furthermore, in response to CD3e/CD28 stimulation, Abcg1<sup>−/−</sup> thymic iNKT cells showed reduced production of IL-4 but increased production of IFN-γ. Our results demonstrate that changes in intracellular cholesterol homeostasis by ABCG1 profoundly impact iNKT cell development and function. *The Journal of Immunology, 2012, 189: 5129–5138.

N
atural killer T cells are a unique subset of T lymphocytes that share characteristics with both NK cells and conventional T cells. There are two main classes of NKT cells, type I and type II. Type I NKT cells, also referred to as invariant NKT (iNKT) cells, express an invariant TCR (iTCR) α-chain, utilizing Vo14Jo18 in mice and Vo24Jo18 in humans. This iTCR α-chain is paired with a limited MHC class I- and class II-reactive T cells, which recognize peptide Ags. iNKT cells recognize glycolipid Ags presented by CD1d, a MHC class I-like molecule (1). At least two classes of glycolipids have been reported to bear antigenic activity for iNKT cells, as follows: glycosphingolipids, as exemplified by Ags found in *Sphingomonas* bacteria (2, 3), and diacylglycerols, found, for example, in *Burrelia* bacteria (4). There are reports that other types of Ags, including cholesterol-containing molecules from *Helicobacter pylori*, are recognized by iNKT cells (5). The best-studied Ag for iNKT cells is the glycosphingolipid, α-galactosylceramide (α-GalCer) (6). Upon activation with α-GalCer, iNKT cells are able to produce large quantities of both Th1 cytokines (IFN-γ) and Th2 cytokines (IL-4, IL-10, and IL-13) (7, 8). Thus, iNKT cells can modulate immunity in a broad range of diseases and conditions, including atherosclerosis, autoimmunity, cancer, diabetes, allergy, and infection (7, 8).

ATP-binding cassette (ABC) transporters are transmembrane proteins that facilitate the transport of specific substrates across the membrane in an ATP-dependent manner (9). ABC transporter G1 (ABCG1) is a member of the ABC transporter family that regulates cholesterol homeostasis in the cell (10). Cholesterol homeostasis is crucial for the growth and survival of cells, because cholesterol is a key component of cell membranes and lipid rafts (11). ABCG1 is expressed in many tissues, including spleen, brain, lung, and kidney, and in many cell types, including lymphocytes, myeloid cells, and endothelial cells (12). Whereas ABCG1 can localizes to the plasma membrane, it resides mostly intracellularly. Although initial studies suggested that the main function of ABCG1, similar to the other cholesterol transporter ABC transporter A1 (ABCA1), is to promote cholesterol efflux from cells (12, 13), recent reports by us and others show that ABCG1 is also important for the intracellular transport of cholesterol (14, 15). We previously reported that ABCG1 regulates the transfer of cholesterol from outer to inner membrane leaflets in secretory granules, including insulin granules in the pancreas (14). A recent study by Tarling and Edwards (15) has demonstrated that ABCG1 localizes to endocytic vesicles to facilitate the redistribution of intracellular cholesterol away from the endoplasmic reticulum. Thus, a key function of ABCG1 may be to regulate membrane cholesterol content to facilitate proper membrane fluidity and cholesterol homeostasis.

ABCG1 expression in immune cells, such as macrophages and lymphocytes, impacts their function. ABCG1-deficient macrophages display increased inflammatory activity (16, 17) in response to LPS (18), and when loaded with cholesterol (19). We (20) and others (21) have reported that changes in cholesterol and lipid raft content in the absence of ABCG1 increase TCR signaling and proliferation of CD4<sup>+</sup> T cells. Like other lymphocytes, iNKT cells express ABCG1; however, the role of ABCG1 and cholesterol homeostasis in iNKT cell biology is not known. In this study, we demonstrate that changes in intracellular cholesterol homeostasis by ABCG1 profoundly impact thymic iNKT cell development and function.

Materials and Methods

Mice

C57BL/6 mice (000664) and B6.129S7-Rag1<sup>tm1Mom/j</sup> (002216) mice were purchased from The Jackson Laboratory (Bar Harbor, ME). Abcg1<sup>−/−</sup>/TacZ knock-in mice were purchased from Deltang (San Mateo, CA) and are congenic on a C57BL/6 background. B6.129J-Ptra/BoyAiTac mice (CD45.1 congenic, 004007) were purchased from Taconic Farms (Germantown, NY). Mice were fed a standard rodent chow diet and were housed in microisolator cages in a pathogen-free animal facility of the La Jolla Institute for Allergy and Immunology. All experiments followed guidelines of the La Jolla Institute for Allergy and Immunology Animal Care and Use Committee, and approval for use of rodents was obtained from the La Jolla Institute for Allergy and Immunology according to criteria outlined in the Guide for the Care and Use of Laboratory Animals from the National Institutes of Health. Mice were euthanized by CO2 inhalation.

Reagents

Flow cytometry Abs, including anti-mouse CD45.2 (104), CD4 (RM4-5), TCRβ (H57-597), IL-4 (BV6D-24G2), CD44 (IM7), NK.1.1 (PK136), and CD1d (1B1), were purchased from eBioscience (San Diego, CA). CD45.1 (A20), IFN-γ (XMG1.2), Vβ7 (TR310), and Vβ8.1/2 (MR5-2) were purchased from BD Biosciences (San Jose, CA); CD19 (6D5) and CD8α (5H10) were purchased from Invitrogen (Carlsbad, CA); and neuropilin-1 (NRP-1) (polyclonal) was purchased from R&D Systems (Minneapolis, MN). Allophycocyanin-conjugated CD1d tetramers loaded with PBS-57 (α-GalCer analog) were purchased from the National Institutes of Health Tetramer Facility. PE and Pacific blue-conjugated Ab in PBS at 4˚C overnight. The next day, the plates were washed twice with PBS, and thymocytes were plated at 2 × 10<sup>5</sup> cells/well in RPMI 1640 medium supplemented with 5% FBS and 1% penicillin/streptomycin. Soluble αCD28 Ab (2 µg/ml) and GolgiPlug (BD Biosciences) were added, and the cells were incubated at 37°C for 4 h. Thymocytes were stimulated with PMA (1 µg/ml) and ionomycin (200 ng/ml) for 4 h in the presence of GolgiPlug at 37°C. IL-4 and IFN-γ production by iNKT cells was assessed by flow cytometry.

In vivo BrdU proliferation assay and detection of apoptosis

C57BL/6 (B6) and Abcg1<sup>−/−</sup> mice were injected i.p. with 0.3 mg BrdU (in 100 µl PBS) three times every 4 h. Thymus were harvested the next day, and single-cell suspensions were stained with fluorophore-conjugated Abs and CD1d tetramer. After cell surface staining, cells were analyzed for BrdU incorporation using FFITC or allophycocyanin BrdU flow kit (BD Biosciences), according to the manufacturer’s instructions. Apoptosis of thymic iNKT cells was measured by flow cytometry using a PE Annexin V Apoptosis Detection Kit 1 (BD Biosciences), according to the manufacturer’s instructions.

Generation of bone marrow chimeras

Recipient mice (Rag1<sup>−/−</sup>) were irradiated in two doses of 450 rad each (for a total of 900 rad) 4 h apart. Bone marrow cells from both femurs and tibias of donor mice (B6.129J and Abcg1<sup>−/−</sup>) were collected under sterile conditions. Bone marrow cells from both femurs and tibias of donor mice were washed, mixed at a 1:1 ratio, and resuspended in PBS for injection. Approximately 5 × 10<sup>6</sup> bone marrow cells from B6.129J and Abcg1<sup>−/−</sup> mice (total 10<sup>7</sup> cells) in 200 µl PBS were delivered retro-orbitally into each recipient mouse. Recipient mice were housed in a barrier facility under pathogen-free conditions before and after bone marrow transplantation. After bone marrow transplantation, mice were provided autoclaved acidified water with antibiotics (trimethoprim-sulfamethoxazole) and were fed autoclaved food. Mice were analyzed 12 wk after bone marrow reconstitution.

Cholesterol content in iNKT cells

Surface Ags on thymocytes from B6 and Abcg1<sup>−/−</sup> mice were stained, as described above, followed by iNKT cell (CD8<sup>−</sup>, TCRβ<sup>+</sup>, CD1d tetramer<sup>+</sup>) sorting with a FACSaria cytometer (BD Biosciences). Approximately 2 × 10<sup>5</sup> events were collected for gas chromatography analysis. Sorted thymic iNKT cells were pelleted by low-spin centrifugation. After several washes with PBS, the cell pellet was extracted with chloroform:methanol (2:1) containing 5-cholestanole as internal standard. Total and free cholesterol content was determined by gas–liquid chromatography and normalized to cellular protein, as previously described (23). Cholesterol ester was calculated as (total cholesterol × free cholesterol) × 1.67. Multiplying by 1.67 corrects for the average fatty acid mass that is lost during saponification.

Quantitative real-time PCR

iNKT cells were FACs sorted from thymus, and total cellular RNA was collected with an RNAeasy Plus Micro Kit, according to the manufacturer’s protocol (Qiagen, Valencia, CA). RNA purity and quantity were measured with a nanodrop spectrophotometer (Thermo Scientific). Approximately 500 ng RNA was used for synthesis of cDNA with an Iscript cDNA Kit (Biorad) and a MyiQ Single-Color Real-Time PCR Detection System (Bio-Rad) and TaqMan Gene Expression Mastermix and ABCG1 and ABCA1 TaqMan primers (Invitrogen). Data were analyzed and presented on the basis of the relative expression method (24). The formula for this calculation is as follows: relative expression = 2<sup>−[ΔCt<sub>2</sub>−ΔCt<sub>1</sub>]</sup> where ΔCt<sub>1</sub> is the difference in the threshold cycle between the gene of interest and the housekeeping gene (18S), S is the Abcg1<sup>−/−</sup> mouse, and C is the B6 control mouse.

Statistical analysis

Data for all experiments were analyzed with Prism software (GraphPad, San Diego, CA). Unpaired Student’s t test was used for comparison of experimental groups. The p values <0.05 were considered statistically significant.

Results

Abcg1<sup>−/−</sup> mice display impaired iNKT cell development

To investigate the impact of ABCG1 deficiency on iNKT cell development, iNKT cell frequencies in thymus, liver, and spleen of four- to six-week-old Abcg1<sup>−/−</sup> and control B6 mice were assessed by flow cytometry (Fig. 1A, 1B). Abcg1<sup>−/−</sup> mice had impaired thymic iNKT cell development.
**FIGURE 1.** Abcg1−/− mice display reduced iNKT cell frequencies in thymus and liver. (A) Thymocytes, liver mononuclear cells, and splenocytes from four- to six-week-old wild-type B6 and Abcg1−/− mice (n = 9) were stained with fluorophore-conjugated Abs and CD1d tetramer. Representative contour plots show CD19−, CD8α+ TCRβ+, CD1d-tetramer+ iNKT cells. Bar graphs show (B) frequency and (C) total cell number of iNKT cells in thymus, liver, and spleen (iNKT cells [%]: % of live cells). Data are pooled from two to three independent experiments (three to five mice per group for each experiment) with similar results. (D) Graph shows the frequency of NRP-1+, CD69− iNKT cells in spleen. Representative data of two independent experiments with four-week-old mice (five to six mice per group) are shown. (E) Thymocytes, liver mononuclear cells, and splenocytes from B6 (n = 5) and Abcg1−/− mice (n = 5) were stained with fluorophore-conjugated CD19, CD8α, TCRβ, VB7, VB8.1/2, and VB2 Abs, and CD1d tetramer, and analyzed by flow cytometry. Graphs show frequencies of VB7+ (top), VB8.1/2+ (middle), and VB2+ (bottom) B6 and Abcg1−/− iNKT cells in thymus, liver, and spleen. (F) Graphs show absolute cell numbers of VB7+ B6 (n = 4) and Abcg1−/− (n = 4) iNKT cells in thymus, liver, and spleen. Data are representative of two independent experiments. Error bars represent means ± SEM. Asterisks denote the significance of differences between groups (*p < 0.05, **p < 0.01, ***p < 0.001, two-tailed Student t test).
significantly lower frequencies of iNKT cells in both thymus and liver compared with control mice (Fig. 1A, 1B). Absolute cell numbers of iNKT cells in thymus and liver were also lower in Abcg1−/− mice compared with control mice (Fig. 1C). A similar tendency was observed in the spleen; however, this did not reach statistical significance in all experiments (Fig. 1A–C). Recently, Milpied et al. (25) reported that recent thymic emigrant iNKT cells express NRP-1 and lack CD69. To determine whether the Abcg1−/− mice had impaired export of iNKT cells from thymus, we examined the expression of NRP-1 and CD69 in splenic iNKT cells of Abcg1−/− and control mice. As shown in Fig. 1D, the frequency of NRP-1+/CD69− iNKT cells in spleen of Abcg1−/− mice was significantly lower compared with control mice. Overall, these data suggest that ABCG1 deficiency reduces the production and thymic egress of iNKT cells.

iNKT cells can be divided into CD4+/CD4− subsets, and into subpopulations that express NK1.1, which is associated with NKT cell development via a cell-intrinsic mechanism. (26) We therefore measured expression of CD4 and NK1.1 on iNKT cells in thymus and spleen of Abcg1−/− and control mice by flow cytometry. We did not observe any differences in the percentages of these phenotypic iNKT cell subsets in either organ (Supplemental Fig. 1).

The invariant Vε14α1.18 TCR chain of iNKT cells is paired with a restricted set of β-chains containing mainly Vβ8.1/2, Vβ7, and Vβ2, with diverse CDR3 regions (1). There are data suggesting that Vβ7+ iNKT cells have a higher affinity for the endogenous ligand(s) presented during positive selection of iNKT cells in the thymus (27). Thus, the frequency of Vβ7+ iNKT cells has been used as a surrogate marker for the overall avidity for the TCR toward its endogenous selecting ligand(s) in the thymus. To determine whether ABCG1 deficiency could impact the selection of iNKT cells in the thymus, we first analyzed Vβ7+ iNKT cells in Abcg1−/− mice. As shown in Fig. 1E, the percentages of Vβ7+ iNKT cells in thymus, liver, and spleen of Abcg1−/− mice were significantly higher than in the control B6 mice. Next, we analyzed Vβ8.1/2+ and Vβ2+ iNKT cells in these organs and found that in thymus and spleen of Abcg1−/− mice, the percentages of Vβ8.1/2+ and Vβ2+ iNKT cells were significantly lower than in the B6 mice, which is in line with the increased frequency of Vβ7+ iNKT cells in the Abcg1−/− mice (Fig. 1E). In liver, the percentage of Vβ8.1/2+ iNKT cells was significantly lower in Abcg1−/− mice compared with B6 mice; however, the percentages of Vβ2+ iNKT cells in Abcg1−/− mice and B6 mice were comparable (Fig. 1E). Next, we determined the absolute cell numbers of Vβ7+ iNKT cells in thymus, liver, and spleen of Abcg1−/− mice. In line with the reduced total iNKT cell frequency in thymus of Abcg1−/− mice compared with control B6 mice (Fig. 1A, 1B), the absolute cell number of Vβ7+ iNKT cells in thymus was also significantly lower in Abcg1−/− mice (Fig. 1F). In liver, the absolute cell number of Vβ7+ iNKT cells tended to be lower in Abcg1−/− mice, but the

**FIGURE 2.** ABCG1 deficiency affects iNKT cell development via a cell-intrinsic mechanism. (A) Thymocytes from B6 mice (n = 5) and Abcg1−/− mice (n = 4) were stained with CD4, CD8α, and CD1d Abs and analyzed by flow cytometry. Bar graph shows mean fluorescence intensity (MFI) of CD1d on CD4+CD8+ thymocytes from either B6 (n = 4) or Abcg1−/− (n = 4) mice in the presence of titrated amounts of α-GalCer in vitro. After 18 h, IL-2 production was detected by ELISA. Data are representative of two independent experiments with similar results. (B) iNKT cell hybridoma DN3A4-1.2 cells were cocultured with thymocytes from either B6 (n = 4) or Abcg1−/− (n = 4) mice with 1:1 mixed bone marrow cells from CD45.1+ B6.SJL and CD45.2+ Abcg1−/− donor mice. Single-cell suspension from thymus was analyzed by flow cytometry 12 wk following reconstitution. (C) Representative contour plots show CD19−, CD8α−, TCRβ−, CD1d-tetramer+ iNKT cells, which are gated on CD45.1+ and CD45.2+ to identify Abcg1−/− B6.SJL and Abcg1−/− iNKT cells, respectively. (D) Bar graph shows percentages of Abcg1−/− B6.SJL and Abcg1−/− iNKT cells in thymus. Data are pooled from three independent experiments (three to four mice per group for each experiment) with similar results. (E) Graph shows frequency of Vβ7+ CD45.1+ B6 and CD45.2+ Abcg1−/− iNKT cells in thymus. Data are pooled from two independent experiments (three mice per group for each experiment) with similar results (**p < 0.01, ***p < 0.001).
difference was not statistically significant ($p = 0.067$) (Fig. 1F). As the frequencies of iNKT cells in spleen of $Abcg1^{-/-}$ mice and B6 mice were comparable (Fig. 1A, 1B) and $Abcg1^{-/-}$ mice had a higher percentage of $\text{Vb}^{7^+}$ iNKT cells in spleen (Fig. 1E), the absolute cell numbers of $\text{Vb}^{7^+}$ iNKT cells in spleen were significantly higher in $Abcg1^{-/-}$ mice (Fig. 1F). These data demonstrate that thymic selection of $\text{Vb}^{7^+}$ iNKT cells is favored in the absence of ABCG1.

**ABCG1 deficiency affects iNKT cell development via a cell-intrinsic mechanism**

A critical factor driving iNKT cell development in the thymus is the generation of a CD1d-restricted iTCR by CD4$^+$CD8$^+$ double-positive (DP) cortical thymocytes (28, 29). Once a DP thymocyte expressing an iTCR interacts with a CD1d-expressing DP cortical thymocyte that presents endogenous selecting ligand(s), the iTCR-expressing DP thymocyte is positively selected to enter the thymic iNKT cell precursor pool (30). Subsequently, these iNKT cell precursors undergo a series of proliferation and differentiation/maturation stages (31). Because iNKT cells are positively selected by DP thymocytes, we examined whether DP thymocytes from $Abcg1^{-/-}$ mice had lower CD1d expression. If so, this would be a likely explanation for the observed decrease in iNKT cell frequency. As shown in Fig. 2A, DP thymocytes from $Abcg1^{-/-}$ and B6 mice had similar levels of surface CD1d expression. Next, to investigate whether ABCG1 deficiency affects CD1d-mediated lipid Ag presentation, we incubated the iNKT cell hybridoma DN3A4-1.2 with thymocytes isolated from either $Abcg1^{-/-}$ or B6 mice in the presence of titrated amounts of $\alpha$-GalCer in vitro. We found that $Abcg1^{-/-}$ thymocytes were as efficient as B6 thymocytes at stimulating IL-2 production by iNKT cell hybridomas (Fig. 2B). Overall, these results show that the impairment in iNKT cell development observed in $Abcg1^{-/-}$ mice was not due to changes in CD1d surface expression on DP thymocytes or their CD1d-mediated Ag presentation.

To determine whether the impact of ABCG1 deficiency on iNKT cell development is mediated through cell-intrinsic factor(s), we used a mixed bone marrow chimera approach. Irradiated Rag1$^{-/-}$ mice were reconstituted with both CD45.1$^+$ B6.SJL and CD45.2$^+$ $Abcg1^{-/-}$ bone marrow mixed at a 1:1 ratio and analyzed 12 wk after reconstitution. We did not observe any difference in the frequency of $Abcg1^{-/-}$ and B6 DP thymocytes (Supplemental Fig. 2A) or in their surface CD1d expression in the chimeric mice (Supplemental Fig. 2B). However, when analyzing iNKT cells in the thymus, we found that $\sim$3-fold fewer iNKT cells developed from the $Abcg1^{-/-}$ bone marrow than from the B6 bone marrow (Fig. 2C, 2D). These results demonstrate that the impact of ABCG1 deficiency on iNKT cell development in the thymus is cell intrinsic.

To determine whether the increased frequency of $\text{Vb}^{7^+}$ iNKT cells in $Abcg1^{-/-}$ mice (Fig. 1E) was also caused by a cell-intrinsic mechanism, we evaluated the percentage of $\text{Vb}^{7^+}$ iNKT cells in the 1:1 mixed bone marrow chimeric mice. $Abcg1^{-/-}$-derived iNKT cells in the thymus of the chimeric mice displayed a higher frequency of $\text{Vb}^{7+}$ population compared with B6-derived iNKT cells (Fig. 2E). These data demonstrate that thymic selection of $\text{Vb}^{7^+}$ iNKT cells is favored in the absence of ABCG1 via an iNKT cell-intrinsic mechanism.

**ABCG1 deficiency affects the maturation of iNKT cells in the thymus**

After positive selection in thymus, iNKT cells proliferate and differentiate/mature along stages that are defined by the surface expression of CD44 and NK1.1 (31). Cells with a stage 1 phe-
notype (CD44\textsuperscript{low} NK1.1\textsuperscript{−}) are followed by stage 2 cells, which have increased CD44 expression (CD44\textsuperscript{high} NK1.1\textsuperscript{−}). Stage 1 and stage 2 iNKT cells are highly proliferative (32, 33). The upregulation of NK1.1 expression by iNKT cells marks stage 3 (CD44\textsuperscript{high} NK1.1\textsuperscript{+}) cells, which are mature but less proliferative (32, 34). Whereas most iNKT cells exit the thymus at stage 2 and complete their maturation in the periphery, some enter stage 3 in the thymus and remain as long-term thymus-resident iNKT cells (31). To determine where during iNKT cell development ABCG1 plays a role, we evaluated the developmental stages of iNKT cells in the 1:1 mixed bone marrow chimeric mice. The percentage of Abcg1\textsuperscript{−/−} iNKT cells in stage 1 (CD44\textsuperscript{low} NK1.1\textsuperscript{−}) was ~2-fold larger compared with B6 iNKT cells, whereas the percentage of iNKT cells in stage 2 (CD44\textsuperscript{high} NK1.1\textsuperscript{−}) was reduced by 33%. There were no differences in the percentages of stage 3 (CD44\textsuperscript{high} NK1.1\textsuperscript{+}) iNKT cells between both genotypes (Fig. 3A, 3B). We calculated the absolute cell numbers of Abcg1\textsuperscript{−/−} and B6 iNKT cells at these three maturation stages, and, in line with the reduced relative frequency of Abcg1\textsuperscript{−/−} iNKT cells in the thymus of the chimeric mice (Fig. 2C, 2D), the total number of Abcg1\textsuperscript{−/−} iNKT cells was dramatically reduced at stages 2 and 3 compared with B6 iNKT cells (Fig. 3C). Subsequently, we analyzed V\textbeta\textsuperscript{7+} iNKT cells in stage 1–3 of thymic development in Abcg1\textsuperscript{−/−} mice. Similar to the observed increase in the frequency of total thymic V\textbeta\textsuperscript{7+} iNKT cells in Abcg1\textsuperscript{−/−} mice (Fig. 1E), the frequencies of V\textbeta\textsuperscript{7+} iNKT cells in all three maturation stages were significantly higher in Abcg1\textsuperscript{−/−} mice than in B6 mice (Fig. 3D). These data indicate that ABCG1 deficiency impairs the proper maturation of iNKT cells at early stages of iNKT cell development.

Abcg1\textsuperscript{−/−} iNKT cells have reduced proliferation

To determine whether the reduced frequency of iNKT cells in the absence of ABCG1 is due to a decrease in proliferation, we measured proliferation of thymic iNKT cells at different maturation stages in vivo in Abcg1\textsuperscript{−/−} and B6 control mice by BrdU incorporation. In Abcg1\textsuperscript{−/−} mice, the frequency of BrdU\textsuperscript{+} iNKT cells at stages 1 and 2 was significantly reduced compared with iNKT cells from B6 mice (Fig. 4A, 4B). In stage 3, the frequency of BrdU\textsuperscript{+} iNKT cells also tended to be lower in Abcg1\textsuperscript{−/−} mice, but the difference was not statistically significant ($p = 0.051$) (Fig. 4A, 4B). Next, we measured BrdU incorporation of V\textbeta\textsuperscript{7+} iNKT cells in Abcg1\textsuperscript{−/−} and B6 mice. In line with the reduced proliferation of total iNKT cells in Abcg1\textsuperscript{−/−} mice (Fig. 4A, 4B), the frequency of BrdU\textsuperscript{+} V\textbeta\textsuperscript{7+} iNKT cells was significantly lower in Abcg1\textsuperscript{−/−} mice compared with B6 mice (Supplemental Fig. 4). To investigate whether increased cell death also contributes to the reduced iNKT cell numbers in the absence of ABCG1, we examined apoptosis of Abcg1\textsuperscript{−/−} and B6 iNKT cells at different stages of thymic development by annexin V staining. We found that the percentages of apoptotic (annexin V\textsuperscript{+} live) iNKT cells at stage 1–3 in Abcg1\textsuperscript{−/−} and B6 mice were comparable (Fig. 4C, 4D). These results indicate that the reduced frequency of iNKT cells...
in thymus in the absence of ABCG1 is not due to increased cell death but reduced proliferation, particularly during the early stages of development.

**ABCG1 deficiency affects lipid raft content in iNKT cells**

We next measured the cholesterol content in iNKT cells isolated from thymus of B6 and Abcg1<sup>2/2</sup> mice using gas chromatography. Data are pooled from three independent experiments (3 samples per group for each experiment) with similar results. We found no significant changes in the cholesteryl ester, free cholesterol, or total cholesterol content in Abcg1<sup>2/2</sup>iNKT cells (Fig. 5A). However, as ABCG1 is important in intracellular cholesterol transport (14, 15) and cholesterol is an important component of membrane lipid rafts (11), we measured lipid raft content in thymic iNKT cells. Lipid rafts are specialized regions of the cell membrane that are rich in cholesterol and gangliosides.

**FIGURE 5.** Abcg1<sup>−/−</sup>iNKT cells display no change in cholesterol content, but have lower lipid raft content. (A) iNKT cells were FACS sorted from thymus of B6 and Abcg1<sup>−/−</sup> mice (n = 9; 27 mice, 3 mice were pooled for each sample per group), and free cholesterol (FC), cholesteryl ester (CE), and total cholesterol (TC) were measured by gas chromatography. Data are pooled from three independent experiments (3 samples per group for each experiment) with similar results. (B and C) Thymocytes from B6 (n = 4) and Abcg1<sup>−/−</sup> (n = 4) mice were stained with fluorophore-conjugated Abs, CD1d tetramer, and CT-B, and analyzed by flow cytometry. (B) Representative plot shows lipid raft staining (CT-B) of iNKT cells in thymus. (C) Graph shows mean fluorescence intensity (MFI) of CT-B of iNKT cells in thymus. Data are representative of two independent experiments with similar results (**p < 0.01).
and act as platforms to colocalize proteins involved in intracellular signaling pathways (35, 36). In contrast to the comparable cholesterol levels, the lipid raft content of Abcg1−/− NKT cells in thymus was 43% lower than in B6 NKT cells (Fig. 5B, 5C). These results suggest that ABCG1 plays a role in regulation of membrane lipid raft content in thymic NKT cells, which is most likely important for their proper development.

**ABCG1 deficiency affects cytokine production of NKT cells**

Because Abcg1−/− NKT cells have reduced lipid raft content (Fig. 5B, 5C) and the TCR is associated with lipid rafts (37), we next investigated whether deficiency of ABCG1 in NKT cells would affect their TCR-driven activation. We stimulated thymocytes from B6:Abcg1−/−:1:1 mixed bone marrow chimeric mice with plate-bound αCD3ε and soluble costimulatory αCD28 Ab in vitro and measured IL-4 and IFN-γ production of thymic NKT cells by intracellular staining. We found that CD45.2+ Abcg1−/− NKT cells had reduced IL-4 production, but enhanced IFN-γ production compared with CD45.1+ B6 NKT cells (Fig. 6A, 6B). Previous studies have shown that stage 1 and stage 2 NKT cells produce abundant IL-4, but less IFN-γ, whereas stage 3 NKT cells make more IFN-γ, but less IL-4 (32, 34, 38). Our results demonstrate that the frequency and the total cell number of stage 2 NKT cells are reduced in the absence of ABCG1 (Fig. 3A–C). Therefore, the diminished production of IL-4 by Abcg1−/− NKT cells might be due to the lower percentages of the potent IL-4 producer stage 2 NKT cells in the absence of ABCG1. To address this possibility, we stimulated thymocytes from Abcg1−/− and B6 mice with αCD3ε and αCD28 Abs in vitro and measured IL-4 and IFN-γ production of thymic NKT at different stages by intracellular staining. Stage 2 and stage 3 Abcg1−/− NKT cells produced significantly less IL-4 and more IFN-γ compared with B6 control (Fig. 6C), demonstrating that the altered cytokine production of Abcg1−/− NKT cells is not due to the reduced percentages of stage 2 NKT cells in the absence of ABCG1. Furthermore, to elucidate that the changes in the cytokine production by NKT cells in the absence of ABCG1 are related to TCR triggering, we stimulated thymocytes from Abcg1−/− and B6 mice in vitro with PMA/ionomycin, which bypasses TCR triggering to induce activation. We then measured IL-4 and IFN-γ production of thymic NKT cells by intracellular staining. As seen in Fig. 6D, PMA/ionomycin stimulation induced IL-4 and IFN-γ production by Abcg1−/− NKT cells to a similar degree as in the B6 NKT cells, indicating that Th1-biased cytokine production we observed in Abcg1−/− NKT cells is indeed related to TCR triggering. Overall, these results demonstrate that deficiency of ABCG1 in NKT cells skews their cytokine production, leading to a Th1 bias following TCR-driven activation.

**Discussion**

In this study, we demonstrate that changes in cholesterol homeostasis caused by the absence of ABCG1 impair NKT cell development. ABCG1-deficient thymic NKT cells displayed reduced proliferation in vivo and defective maturation during the early stages of development. Considering the number of thymic NKT cells, the developmental block was particularly evident at stage 2, although the reduced proliferation of stage 1 cells most likely contributes to the deficit. Moreover, in the absence of ABCG1, thymic NKT cells had reduced membrane lipid raft content, which was accompanied by a Th1-biased cytokine production in response to TCR stimulation. The defects were cell intrinsic, meaning that they occur in the NKT cell precursor rather than in the DP thymocyte responsible for NKT cell-positive selection. Therefore, although it is theoretically possible that a cholesterol-containing compound is an important self-ligand mediating positive selection, our results rule out differences in self-ligand presentation as the responsible factor. In addition, thymic selection of Vβ7+ NKT cells was favored in the absence of ABCG1 via an NKT cell-intrinsic mechanism. Importantly, to our knowledge, our work illustrates for the first time an NKT cell-intrinsic modulation of the TCR Vβ repertoire during thymic selection. Furthermore, to our knowledge, our work is the first to demonstrate that changes in intracellular cholesterol homeostasis profoundly impact NKT cell development and function.

We (20) and Bensinger et al. (21) have previously reported that alterations in intracellular cholesterol homeostasis in the absence of ABCG1 lead to a hyperproliferative phenotype of conventional T cells. In our previous study, we showed that ABCG1-deficient CD4+ T cells displayed enhanced TCR signaling and proliferation as a result of increased cholesterol and lipid raft content (20). In contrast, this study reveals an opposite role of ABCG1 in NKT cells, as ABCG1-deficient NKT cells displayed decreased proliferation and lower membrane lipid raft content. NKT cells differ from naive CD4+ T cells in that they have an activated/memory phenotype and they produce large amounts of both Th1 and Th2 cytokines following activation with glycolipid Ags (8). Therefore, it is plausible that NKT cells have differences in cholesterol metabolism and, as such, different requirements for cholesterol homeostasis than do CD4+ T cells. Excess cholesterol is exported out of the cell by the cholesterol transporters ABCA1 and ABCG1 (39, 40). ABCA1 effluxes cholesterol to lipid-poor apolipoprotein A1 (41), whereas ABCG1 promotes cholesterol efflux to mature high-density lipoprotein particles (13). NKT cells express both ABCA1 and ABCG1 (Supplemental Fig. 3A, 3B). ABCA1 expression is enhanced in Abcg1−/− NKT cells compared with B6 NKT cells (Supplemental Fig. 3B). This is not surprising, because many previous studies have shown that genetic deletion of one cholesterol transporter, either ABCA1 or ABCG1, is compensated for by an upregulation of the other transporter (20, 42, 43). Nonetheless, neither ABCA1 nor ABCG1 can fully compensate for the loss of the other (10). However, we cannot rule out the possibility that changes in ABCA1 expression contributed to our observed findings of altered NKT cell development and function in Abcg1−/− mice. Whereas, in the absence of ABCG1, the total cholesteryl ester content of CD4+ T cells increases (20), the total cholesteryl ester of NKT cells is unchanged (Fig. 5A). These results suggest that, in terms of regulating cholesteryl ester content, ABCA1 can substitute for the lack of ABCG1 in NKT cells, but not in T cells. Future studies of the role of ABCA1 in NKT cells using floxed mice may be useful to delineate the different roles of these two transporters in NKT cell development.

Apart from cholesterol efflux, ABCG1 is also important for intracellular cholesterol transport (14, 15). Cholesterol is an essential component of membrane lipid rafts (11). Because NKT cells have a reduction in the lipid raft context (Fig. 5B, 5C) without any changes in the overall cholesterol content (Fig. 5A) in the absence of ABCG1, the critical role of ABCG1 in NKT cells seems to be the regulation of the intracellular transport of cholesterol. Miguel et al. (44) have recently shown that the amount of membrane lipid rafts present in CD4+ T cells correlates closely with immunological synapse formation and CD4+ T cell proliferation and activation. Therefore, based on our data, we hypothesize that ABCG1 deficiency causes a decrease in the transport of cholesterol to the cell membrane, affecting lipid rafts, which impacts NKT cell development and function.

Our results demonstrate that, in the absence of ABCG1, thymic selection of Vβ7+ NKT cells is favored in a cell-intrinsic manner. Previous studies have shown that Vβ7+ NKT cells have a lower
affinity toward α-GalCer (45), whereas, based on the analysis of CD1d+ heterozygous mice, they may have a higher affinity for the endogenous ligand(s) for the positive selection of NKT cells in thymus (27). Therefore, the frequency of thymic Vβ7+ NKT cells may be a surrogate marker for the overall avidity of the iTCR toward its endogenous selecting ligand(s) in the thymus. In previous studies, which showed that the thymic selection of the Vβ7+ NKT cells was favored, the reduced avidity of the iTCR toward the selecting ligand(s) was due to reduced expression of CD1d on DP thymocytes (27). However, in our study, the surface expression levels of CD1d on DP thymocytes in Abcg1−/− mice were unchanged (Fig. 2A). Furthermore, the expression levels of the TCR/CD3 complex were similar in the Abcg1−/− NKT cells compared with control data (not shown). As the effects we observed were NKT cell intrinsic (Fig. 2E), this altogether suggests that the differences in the avidity of the iTCR–CD1d interaction in the Abcg1−/− mice are due to changes in the iTCR itself. Based on our data, we hypothesize that the alterations in the lipid raft content in the absence of ABCG1 modify the distribution of the TCR in NKT cells so that it is less colocalized in lipid rafts. These changes may make the iTCR less sensitive to the endogeneous ligand(s) presented by CD1d for the positive selection of NKT cells in thymus. Such a reduction may favor the selection of relatively high-affinity Vβ7+ NKT cells in the thymus and lead to reduced export of NKT cells to the periphery. Changes in the composition/organization of the iTCR also alter cytokine production of NKT cells. More work is needed, however, to examine how ABCG1 deficiency leads to a Th1-biased cytokine production.

In summary, we demonstrate a novel role for ABCG1-mediated cholesterol homeostasis in NKT cell development. NKT cells have been implicated in the development of atherosclerosis, rheumatoid arthritis, several forms of allergy, as well as autoimmunity (7, 8). All of these diseases have known or proposed lipid constituents that increase risk of disease development. For example, ABCG1-deficient (43, 46), as well as NKT cell-deficient mice are protected from atherosclerosis development (47–51). Therefore, linking the role of lipid transporters and glycolipid-sensitive NKT cells could lead to the development of entirely new therapeutic approaches for diseases that have a hyperlipidemic component, such as atherosclerosis.
