Suppressor of Cytokine Signaling 1 DNA Administration Inhibits Inflammatory and Pathogenic Responses in Autoimmune Myocarditis

Kazuko Tajiri,*§ Kyoko Imanaka-Yoshida,∗§§ Akihiro Matsubara,*§§§ Yusuke Tsujimura,* Michiaki Hiroe,‖ Tetsuji Naka,† Nobutake Shimojo,‡ Satoshi Sakai,‡ Kazutaka Aonuma,‡ and Yasuhiro Yasutomi∗§§

Myocarditis and subsequent dilated cardiomyopathy are major causes of heart failure in young adults. Myocarditis in humans is highly heterogeneous in etiology. Recent studies have indicated that a subgroup of myocarditis patients may benefit from immunotargeted therapies, because autoimmunity plays an important role in myocarditis as well as contributing to the progression to cardiomyopathy and heart failure. Suppressor of cytokine signaling (SOCS) 1 plays a key role in the negative regulation of both TLR- and cytokine receptor-mediated signaling, which is involved in innate immunity and subsequent adaptive immunity. In this study, we investigated the therapeutic effect of SOCS1 DNA administration on experimental autoimmune myocarditis (EAM) in mice. EAM was induced by s.c. immunization with cardiac-specific peptides derived from α myosin H chain in BALB/c mice. In contrast to control myocarditis mice, SOCS1 DNA-injected mice were protected from development of EAM and heart failure. SOCS1 DNA administration was effective for reducing the activation of autoreactive CD4+ T cells by inhibition of the function of Ag-presenting dendritic cells. Our findings suggest that SOCS1 DNA administration has considerable therapeutic potential in individuals with autoimmune myocarditis and dilated cardiomyopathy. The Journal of Immunology, 2012, 189: 2043–2053.

Dilated cardiomyopathy (DCM) is a potentially lethal disorder of various etiologies for which no treatment is currently satisfactory (1); it often results from enteroviral myocarditis (2, 3). Many patients show heart-specific autoantibodies (3, 4), and immunosuppressive therapy can improve cardiac function in DCM patients who show no evidence of viral or bacterial genomes in heart biopsy samples (5). These observations suggest that autoimmunity plays an important role in myocarditis.

Abbreviations used in this article: BMDC, bone marrow-derived dendritic cell; DC, dendritic cell; dnSOCS1, dominant-negative suppressor of cytokine signaling 1; EAM, experimental autoimmune myocarditis; FS, fractional shortening; KO, knock-out; LV, left ventricular; LVEDd, left ventricular end-diastolic dimension; LVEFSd, left ventricular end-systolic dimension; MyHC-α, cardiac myosin-specific peptide; pdnSOCS1, plasmid vector encoding dominant-negative suppressor of cytokine signaling 1; psSOCS1, plasmid vector encoding suppressor of cytokine signaling 1; QRT-PCR, quantitative real-time RT-PCR; SOCS, suppressor of cytokine signaling.

but also innate immunity by suppressing hyperactivation of macrophages and DCs.

In this study, we describe the therapeutic effect of SOCS1 DNA administration using plasmid DNA encoding SOCS1 for EAM. SOCS1 DNA therapy reduces myocarditis by regulating DC populations during EAM.

Materials and Methods

**Animals**

BALB/c mice and CB17.SCID mice were purchased from CLEA Japan. We used 5–7-wk-old male mice. All animals were cared for according to ethical guidelines approved by the Institutional Animal Care and Use Committee of the National Institute of Biomedical Innovation.

**Immunization protocols**

Mice were immunized with 100 μg cardiac myosin-specific peptide (MyHC-0614-420) Ac-RSLKLMATLSTASYASDR-OH (Toray Research Center) emulsified 1:1 in PBS/CFA (1 mg/ml; H37Ra; Sigma-Aldrich) on days 0 and 7 as described previously (12). For DC immunization, bone marrow-derived DCs (BMDCs) were generated as described (26). BMDCs were pulsed overnight with 10 μg/ml MyHC-α peptide and stimulated for another 4 h with 0.1 μg/ml LPS (Sigma-Aldrich) and 5 μg/ml anti-CD40 (BD Pharmingen) (15). Recipient mice received 2.5 × 10^7 pulsed and activated BMDCs i.p. on days 0, 2, and 4 and were killed 10 d after the first injection.

**Plasmid construction and DNA transfection**

Mouse SOCS1 cDNA and dominant-negative SOCS1 (dnSOCS1) cDNA were subcloned into the mammalian vector pcDNA3.1-myc/His(-) using oligonucleotide primers containing restriction sites for XhoI and EcoRI at the 5′ and 3′ ends, respectively. MyHC-α/CFA-immunized mice were injected i.p. with 100 μg of plasmid DNA in 200 μl PBS on days 0, 5, and 10. BMDC-transfected mice and CD4+ T cell adoptive-transferred SCID mice were treated with plasmid DNA on days 0 and 5.

**Histopathologic examination**

Myocarditis severity was scored on H&E-stained sections using grades from 0–4: 0, no inflammation; 1, <25% of the heart section involved; 2, 25–50%; 3, 50–75%; and 4, >75%. To quantify the fibrotic area, ventricular sections were stained with Sirius Red. The fibrotic area was calculated as the sum of all areas stained positive for Sirius Red divided by the sum of all myocardial areas in each mouse. Two independent researchers scored the slides separately in a blinded manner.

**Flow cytometry**

Heart inflammatory cells were isolated and processed as described (15, 27). Cells were stained using fluorochrome-conjugated mouse-specific Abs against CD45, CD4, CD3ε, CD44, CD46L, and CD40L (BD Biosciences). Samples were analyzed on a FACSCalibur cell sorter (BD Biosciences).

**Measurements of cytokines and chemokines**

Hearts were homogenized in media containing 2.5% FBS. Supernatants were collected after centrifugation and stored at −80°C. For in vitro stimulation assay of primary CD4+ T cells, naive CD4+CD62L+ T cells were isolated from the spleens by MACS (CD4+CD62L+ T Cell Isolation Kit II; Miltenyi Biotec). A total of 1.5 × 10^5 CD4+CD62L+ cells were then stimulated with recombinant mouse IL-2 (R&D Systems) or recombinant mouse IL-12 (R&D Systems). Concentrations of cytokines and chemokines in the heart homogenates or culture supernatants were measured with Quantikine ELISA kits (R&D Systems).

**Proliferative responses of T cells**

Proliferation of T cells was assessed as previously described (28). Briefly, mice were immunized as described above, and the spleens collected on day 14. Cells were cultured with 5 μg/ml MyHC-α for 72 h and pulsed with 0.5 μCi [3H]thymidine 8 h before being measured with a β counter. For in vitro stimulation assay of primary CD4+ T cells, naive CD4+CD62L+ T cells were isolated from the spleens by MACS (CD4+CD62L+ T Cell Isolation Kit II; Miltenyi Biotec). A total of 10^5 CD4+CD62L+ cells were then stimulated with 5 μg/ml anti-CD3ε, 5 μg/ml anti-CD3ε, 1 μg/ml anti-CD28, 50 ng/ml PMA, and 500 ng/ml ionomycin or with 1 μg/ml Con A together with 0.25 × 10^3 DCs. Proliferative responses were assessed after 48 h in 2.5% RPMI 1640 medium by measurement of the [3H]thymidine incorporation.

**Western blot analysis**

Total lysates from CD4+ T cells or DCs were immunoblotted and probed with Abs directed against STAT1 (Santa Cruz Biotechnology) and p-STAT1 protein (Cell Signaling Technology). HRP-conjugated goat anti-rabbit IgG (Bio-Rad) was used to identify the binding sites of the primary Ab.

**Adoptive transfer of T cells**

Splenocytes were collected from diseased mice and cultured with 5 μg/ml MyHC-α for 48 h. A total of 5 × 10^6 CD4+ T cells were purified by using anti-CD4 magnetic beads (Miltenyi Biotec) and injected i.p. into the SCID mice. The mice were killed 10 d after the injection.

**Quantitative real-time RT-PCR**

Total RNA was prepared using TRIzol reagent (Invitrogen) according to the manufacturer’s instructions. cDNA was synthesized from 1 μg total RNA by reverse transcriptase (Takara). Quantitative real-time RT-PCR (QRT-PCR) analysis was performed with LightCycler (Roche Diagnostics). Primers for mouse Socs1 were 5′-GGTTGTGGGATGAT-3′ (sense) and 5′-TCTGTGAGTGGTGAGTGACG-3′ (antisense). Primers for housekeeping gene Hprt were 5′-TCCCCCTGAGACCGGTTT-3′ (sense) and 5′-CC-TGTTCTCATCCTGTA-3′ (antisense). Data were normalized by the level of Hprt expression in each sample.

Echocardiography

Transthoracic echocardiography was performed on animals on day 35 by using a Prosound 06 with a 10-MHz transducer (Aloka). The left ventricular (LV) chamber dimensions were measured from the M-mode. Two independent investigators who conducted the echocardiography were unaware of the treatment status.

**Statistical analysis**

All data were expressed as means ± SEM. Statistical analyses were performed using the two-tailed t test or Mann–Whitney U test for experiments comparing two groups. The p values <0.05 were considered statistically significant.

Results

**SOCS1 DNA administration inhibits the development of EAM**

To examine the effect of in vivo gene delivery of Socs1 on the pathogenesis of EAM, BALB/c mice were injected with a mammalian expression plasmid vector encoding SOCS1 (pSOCS1) during the course of EAM induction (Fig. 1A). QRT-PCR analysis revealed elevated expression of Socs1 in the control EAM heart (Fig. 1B). Importantly, in the SOCS1 DNA-administered mice, Socs1 was strongly expressed in the heart. By day 28, Socs1 gene expression was significantly elevated in the pSOCS1-treated heart as compared with the controls (Supplemental Fig. 1). Gross cardiac enlargement and edema were reduced in mice with EAM that received pSOCS1 as compared with those in control empty plasmid DNA-administered EAM mice (Fig. 1C). The heart-to-body weight ratio in the pSOCS1-injected mice was significantly decreased as compared with that in the control plasmid-administered mice (Fig. 1D). The pSOCS1-injected EAM mice had a significantly lower myocarditis severity score and fewer infiltrating inflammatory cells than did the control plasmid-injected mice (Fig. 1E–G). The empty vector [pcDNA3.1-myc/His(-)] was used as the control and did not have any effects on EAM in our experiments (data not shown).

Recently, Hanada et al. (29) demonstrated that dnSOCS1, which has a point mutation (F59D) in a functionally critical kinase domain of SOCS1, strongly augmented cytokine-dependen tJAK-STAT activation both in vivo and in vitro as an antagonist of SOCS1. We examined the effect of dnSOCS1 on the clinical course of EAM. Mice administered a plasmid vector

Downloaded from http://www.jimmunol.org/ by guest on July 25, 2017
encoding dnSOCS1 (pdnSOCS1) showed augmentation of gross heart enlargement, edema, and heart-to-body weight ratio (Fig. 1C, 1D). However, the myocardial leukocyte infiltration and myocarditis scores were not significantly different between the pdnSOCS1- and control plasmid-administered mice (Fig. 1E–G).

To clarify the adverse effect of dnSOCS1 DNA administration on the development of EAM, we used mice immunized with a tithe amount (10 μg) of MyHC-α instead of the usual amount of peptide for EAM development (Fig. 2A). Those MyHC-α–immunized mice injected with the control plasmid or pSOCS1 did not develop myocarditis (Fig. 2B–F). However, immunized mice injected with pdnSOCS1 developed myocarditis with inflammatory infiltrates (Fig. 2B–F). Thus, administration of pSOCS1 is effective against the development of EAM, and the inhibition of SOCS1 by use of a SOCS1 antagonist adversely affects myocarditis.

**SOCS1 DNA administration prevents progression of heart failure and fibrosis after myocarditis**

Some patients diagnosed with myocarditis after viral, bacterial, or protozoal infection develop heart failure (2). On day 35 of the present experiment, mice immunized with MyHC-α showed increased LV end-diastolic dimensions (LVEDd) and LV end-systolic dimensions (LVESd) and decreased fractional shortening (FS); however, pSOCS1-injected mice showed almost normal chamber size and LV function (Fig. 3A, 3B). In contrast, LV dysfunction and chamber dilatation in pdnSOCS1-administered mice were manifested as significant increases in LVEDd and LVESd and decrease in FS (Fig. 3A, 3B). In these EAM models, on day 35, hearts from myocarditis mice showed interstitial fibrosis without active leukocyte infiltration. The fibrotic area in mice administered pSOCS1 was significantly smaller than that in control plasmid-injected mice (Fig. 3C, 3D). Although pdnSOCS1-injected mice developed severe cardiac fibrosis, the difference between the fibrotic areas in pdnSOCS1- and control plasmid-injected mice was not statistically significant (Fig. 3C, 3D). These inhibitory effects of pSOCS1 on the development of fibrosis and heart failure were considered to be the result of inhibition of myocardial inflammation because myocarditis developed mice injected with pSOCS1 on day 14, 21, and 28 did not show inhibitory effects on fibrosis and heart failure (data not shown).

**Cardiac myosin-specific CD4+ T cell response and cytokine production**

Autoimmune myocarditis is a CD4+ T cell-mediated disease (7, 15). Proliferative responses of CD4+ T cells after in vitro restimulation with MyHC-α were not clearly seen in pSOCS1–injected mice, pdnSOCS1, or control plasmid-injected mice; however, the proliferation of CD4+ T cells from pSOSCS1-injected mice was enhanced (Fig. 4A). Production of IL-2, IL-6, IL-10, IL-17, IL-22, IFN-γ, TNF-α, CCL2, CCL3, CCL5, CCL17, and CXCL10 by CD4+ T cells from EAM mice was enhanced by in vitro restimulation with the MyHC-α epitope peptide. This cardiac-Ag–specific cytokine production by CD4+ T cells was decreased in the supernatants of in vitro MyHC-α–restimulated CD4+ T cells from pSOSCS1–injected mice but
was increased in the supernatants of these cells from pdnSOCS1-administered mice (Fig. 4B). In contrast, cardiac-Ag–specific production of IL-1β, IL-10, and CXCL1 was not detected in the culture supernatants of in vitro-restimulated CD4+ T cells from control plasmid-, pSOCS1-, or pdnSOCS1-injected mice (data not shown). Taken together, these results indicate that SOCS1 DNA

**FIGURE 2.** Increased susceptibility to EAM induced by inhibition of SOCS1. (A) Mice were immunized twice, on days 0 and 7, with 10 μg of MyHC-α emulsified 1:1 in PBS/CFA and treated with pSOCS1, pdnSOCS1, or control plasmid on days 0, 5, and 10. (B) Representative gross hearts (day 14) of naive and 10 μg of MyHC-α–immunized mice treated with the indicated plasmid. (C) Heart-to-body weight ratios of naive and immunized mice (n = 5 to 6 mice/group). (D) Representative H&E-stained sections of hearts from naive and immunized mice. Arrowheads indicate infiltrating cells. Scale bar, 50 μm. (E) Myocarditis severity in heart sections stained with H&E (n = 5 to 6 mice/group). (F) Flow cytometry analysis of CD45+ heart infiltrates of naive and immunized mice (n = 5 mice/group). Data are representative of at least two independent experiments. Error bars represent means ± SEM. *p < 0.05, **p < 0.01 compared with control.

**FIGURE 3.** SOCS1 DNA administration prevents progression to heart failure. (A and B) Echocardiography was performed on naive and immunized mice on day 35. (A) Representative M-mode echocardiograms. Bars indicate LVESd and LVEDd. Bar graphs (B) represent LVEDd and percentage of FS from the indicated animals (n = 9 mice/group). The percentage FS was calculated according to the following formula: FS (%) = (LVEDd − LVEDd)/LVEDd. (C and D) Heart tissue sections were stained with Sirius Red and analyzed for fibrosis at day 35. Representative Sirius Red-stained sections of hearts. Scale bar, 50 μm. (C) Arrowheads indicate fibrotic area. (D) The degree of fibrosis was calculated as the percentage of the fibrotic area in relation to the total heart area (n = 5 mice/group). Data are representative of at least two independent experiments. Error bars represent means ± SEM. *p < 0.05, **p < 0.01 compared with control.
delivery inhibits the activation of myosin-specific CD4+ T cells and strongly suggest that impaired CD4+ Th cell function prevents EAM development in pSOCS1-injected mice after immunization with cardiac self-Ag.

To evaluate whether pSOCS1 administration affects Ag-specific CD4+ T cell function in other models, we injected plasmid DNA into an autoimmune gastritis model and an OVA-immunized model. In the autoimmune gastritis model, gastric-Ag–specific production of IL-2, IL-6, IL-13, IL-17, IL-22, IFN-γ, TNF-α, CCL2, CCL5, CCL17, and CXCL10 by CD4+ T cells was decreased in pSOCS1-administered mice but increased in pdnSOCS1-administered mice (Supplemental Fig. 2). Lower amounts of cytokines (including IL-2, IL-6, IL-13, IFN-γ, TNF-α, CCL2, CCL3, CCL5, CCL17, and CXCL10) were also produced in CD4+ T cells from pSOCS1-injected OVA-immunized mice (Supplemental Fig. 3). These results suggest that pSOCS1 administration may suppress Ag-specific CD4+ T cell activation in various autoimmune diseases and foreign body infections.

SOCS1 DNA administration inhibits the production of proinflammatory cytokines and CD4+ T cell differentiation in the heart

We also examined whether SOCS1 DNA administration has an effect on cytokine and chemokine milieu in the heart. On day 14 after MyHC-α immunization, heart homogenates from pSOCS1-injected mice had significantly decreased amounts of proinflammatory cytokines, including IL-1β and IL-6, and of myelotropic chemokines, including CCL5, CXCL1, and CXCL10 (Fig. 5A). In contrast, hearts from mice injected with pdnSOCS1 showed greatly increased amounts of proinflammatory cytokines and chemokines (Fig. 5A). SOCS1 protein has been shown to regulate T cell differentiation (17, 18). To determine the differentiation of CD4+ T cells during EAM, we examined the heart-infiltrating CD4+ T cell populations by FACS analysis. Activated CD4+ T cells (CD4+CD40L+) and effector memory CD4+ T cells (CD44+CD62L-) were reduced in the pSOCS1-injected mice (Fig. 5B). Thus, protection from EAM in pSOCS1-administered mice is associated with abrogation of proinflammatory cytokines, chemokines, and CD4+ T cell differentiation in the heart.

SOCS1 DNA injection does not have a direct suppressive effect on CD4+ T cell activation

To gain new insights into the mechanism of protection from myocarditis, we investigated whether pSOCS1 therapy directly affects CD4+ T cell activation. Naive T cells (CD4+CD62L+ cells) were isolated from non-EAM mice injected with pSOCS1, pdnSOCS1, or control plasmid, and their primary responses to various stimuli were compared (Fig. 6A). As shown in Fig. 6B, there were no differences in IFN-γ–induced STAT1 activation among these CD4+ T cells. There were also no differences in primary responses to stimulation with anti-CD3ε, anti-CD3ε/anti-CD28, PMA/ionomycin, or Con A presented by mitomycin C-treated wild-type DCs among pSOCS1-, pdnSOCS1-, or control plasmid-treated CD4+ T cells (Fig. 6C). Chong et al. (30) demonstrated that SOCS1-deficient T cells produced substantially greater levels of IFN-γ in response to IL-2 or IL-12. From these findings, we assessed the production of IFN-γ from CD4+ T cells by using the same experiments. In the culture supernatants of

FIGURE 4. Impaired expansion of heart-specific CD4+ T cells in pSOCS1-treated mice. (A) Splenocytes were isolated from naive and EAM mice treated with pSOCS1, pdnSOCS1, or control plasmid on day 14 and restimulated in vitro with MyHC-α or OVA peptide for 72 h. Proliferation was assessed by measurement of [3H]thymidine incorporation. Data represent means ± SEM of triplicates from one of three independent experiments. (B) Cytokines and chemokines in the culture supernatants of splenocytes were measured by ELISA after 48 h of restimulation with MyHC-α or OVA peptide. Data are expressed as mean ± SEM from triplicate culture wells. Results of one of two representative experiments are shown. *p < 0.05 compared with MyHC-α-stimulated control, #p < 0.05 compared with OVA-stimulated control.
In vivo SOCS1 DNA administration inhibits DC function

Although CD4+ T cell differentiation was inhibited in pSOCS1-treated mice (Fig. 5B), our results suggested that in vivo Socs1 gene administration has no direct effect on CD4+ T cell activation (Fig. 6). We therefore investigated whether in vivo pSOCS1 administration inhibits the function of Ag-presenting DCs by stimulation through the TLR pathway. DCs from mice administered pSOCS1, pndlSOCS1, or control plasmid were stimulated with LPS for 24 h (Fig. 7A). STAT1 phosphorylation was attenuated in pSOCS1, pdnSOCS1, or control plasmid-injected mice (Fig. 7B). The production of proinflammatory cytokines, including IL-6, TNF-α, and IFN-γ, was inhibited in DCs from pSOCS1-injected mice and enhanced in DCs from pdnSOCS1-injected mice (Fig. 7C). These results indicate that in vivo administration of SOCS1 DNA has no direct effect on CD4+ T cell activation.

Discussion

There have been no effective fundamental therapies for acute myocarditis; therefore, supportive care for LV dysfunction is the first line of treatment. Because patients generally present days to weeks after the initial viral infection, antiviral therapy has limited applicability in patients with acute viral myocarditis. The long-term sequelae of viral myocarditis appear to be related to abnormal cellular and humoral immunity; therefore, many clinicians believe that immunosuppression is beneficial for myocarditis treatment (2). In this study, we showed that administration of SOCS1 DNA is effective for inhibiting the development of EAM in BALB/c mice, suggesting a novel immunotherapy for myocarditis. To our knowledge, this is the first report showing that gene delivery of Socs1 prevents autoimmune disease.

Animal models have greatly advanced our knowledge of the pathogenesis of myocarditis and inflammatory cardiomyopathy. Infection of BALB/c mice with either Coxackievirus or murine CMV results in the development of acute myocarditis from days 7–14 postinfection that is characterized by myocyte damage due to viral cytotoxicity, and the infectious virus cannot be detected past day 14 of the infection (7). After elimination of viruses, mice showed autoimmune myocarditis, which is associated with mononuclear infiltration of the myocardium and production of autoantibodies to cardiac myosin (7), similar to the pathogenesis of autoimmune myocarditis in humans (3, 4, 33). These autoim-
mune responses are thought to be elicited by two mechanisms. One is molecular mimicry: responses to microbial Ags could result in the activation of T cells that are cross-reactive with self-Ags. Another possibility is bystander activation of autoreactive cells. APCs that have become activated in the inflammatory milieu of a pathogenic infection can stimulate the activation and proliferation of autoreactive T or B cells in a process known as bystander activation (reviewed in Ref. 34). Thus, immune responses to myocytes involving various innate and adaptive immune pathways were recognized during myocarditis development. The cardiac myosin peptide-immunized mouse EAM model reflects human autoimmune myocarditis and heart failure after elimination of infectious pathogens.

Recent studies have indicated that various microbes use the host’s SOCS proteins for manipulating cytokine receptor signaling as one of the strategies to evade immune responses (35, 36). Coxsackievirus usually infects cardiomyocytes and induces the expression of SOCS1 and SOCS3 in cardiomyocytes, which can result in evasion of immune responses and facilitation of virus replication by inhibition of JAK–STAT signaling (32, 37). These findings indicate that it may be harmful to administer SOCS1 DNA in the acute phase of infectious myocarditis because it may augment viral replication by inhibition of IFN signaling. The effect of SOCS1 transduction on viral myocarditis has been examined by Yasukawa et al. (32). The SOCS1-transgenic mice infected with CVB3 showed increased myocardial injury, virus replication, and mortality. In contrast, they also showed that SOCS1 inhibition in the heart through adeno-associated virus-mediated expression of dnSOCS1 increased resistance to the acute cardiac injury caused by CVB3 infection. These results were acceptable because SOCS proteins have emerged as frequent targets of viral exploitation. Furthermore, when administering JAK inhibitors, such as SOCS, active serious infections should have been resolved before the start of treatment. It is considered to be inappropriate to use JAK inhibitors for a person with infectious disease or their possibility with consideration for complication of infection (38–40). In contrast, the overactive autoimmune responses triggered by microbial pathogens can persist after elimination of infectious pathogens (7). Therefore, we examined the efficacy of SOCS1 transfection by using EAM induced by cardiac autoantigen immunization in the absence of viral infection. In the current study, we clearly showed the efficacy of \( \text{Socs1} \) gene transfer as an immunosuppressive therapy for myocarditis under infectious pathogen-free conditions in an EAM mice model. The results of a recent randomized, double-blind, placebo-controlled study showed that immunosuppressive therapy, including prednisone and azathioprine, was effective in patients with myocarditis and inflammatory cardiomyopathy and without evidence of the myocardial viral genome (41). These findings indicate that \( \text{Socs1} \) gene transfer can be effective to treat some clinical
cases of myocarditis and inflammatory cardiomyopathy associated with autoimmunity and without the virus genome in the myocardium, as well as EAM in mice.

In the current study, we demonstrated that the administration of plasmid DNA encoding SOCS1 did not affect autoreactive CD4+ T cell function (Fig. 6) and adoptive transfer of autoreactive CD4+ T cells was able to induce myocarditis in SOCS1 DNA-administered SCID mice (Fig. 8A–D), suggesting that SOCS1 DNA does not suppress either CD4+ T cell recruitment or accumulation of other inflammatory cells in the heart. In contrast, the introduced SOCS1 DNA inhibited the activation of DCs producing proinflammatory cytokines (Fig. 7C). In fact, inhibition of the phosphorylation of STAT1 molecules was observed in DCs from mice injected with SOCS1 DNA (Fig. 7B). In addition, the proliferative responses of CD4+ T cells cocultured with DCs from pSOCS1-treated mice were much weaker than those of cells cultured with DCs from control plasmid-injected mice (Fig. 7E). These results suggest that the inoculated SOCS1 DNA may have been transfected into DCs and impaired DC function in vivo. Contrary to expectations, we could not find evidence of direct transfection into DCs; however, our data do not exclude the possibility of another indirect mechanism.

In the EAM model, activation of TLRs on self-Ag–presenting DCs is essential for the expansion of autoreactive CD4+ T cells to induce myocarditis and heart failure (15). We previously reported that Tlr4 mutant C3H/HeJ mice are resistant to development of EAM (45). Furthermore, IL-1 type 1 receptor signaling on DCs is critical for autoimmune myocarditis development (11). MyD88 is a crucial common adaptor molecule that mediates both TLRs and IL-1 type 1 receptor activation (46, 47), and MyD88 signaling in DCs is critical for the induction of EAM (16). SOCS1 negatively regulates the MyD88-dependent pathway by interacting with both IL-1R–associated kinase and NF-κB (17), which results in a decrease in the induction of inflammatory cytokines such as TNF-α and IL-6. In fact, production of these inflammatory cytokines was inhibited by the administration of SOCS1 DNA in the current study (Fig. 7C). Although nearly all TLRs recruit MyD88, other specific adaptor proteins function downstream of particular TLRs. One such adaptor molecule is Toll/IL-1R domain-containing adaptor protein/Mal. SOCS1 also binds to tyrosine-phosphorylated Mal through its interaction with Bruton’s tyrosine kinase, leading to the suppression of Mal-dependent p65 phosphorylation and transactivation of NF-κB (48). Another important mechanism of the suppression of APC activation by SOCS1 is inhibition of the secondary activated JAK–STAT pathway (49, 50). The Toll/IL-1R domain-containing adaptor protein–inducing IFN-β–IFN-regulatory factor 3 pathway rapidly induces IFN-β, which in turn activates JAK–STAT1 and contributes to the expression of IFN-α.
inducible genes (51). Moreover, Kimura et al. (52) showed that LPS can activate JAK2 and STAT5, which are involved in IL-6 induction, and that SOCS1 selectively inhibits this process. Thus, SOCS1 negatively regulates several activation pathways in DCs. The present study indicates that pSOCS1 administration is a possible therapy against various diseases caused by overshooting of DCs.

IFN-γ has been shown to be a downregulatory cytokine, as evidenced by exacerbated myocarditis in IFN-γR knockout (KO), IFN-γ KO, and T-bet KO mice (9, 53, 54). In contrast, Th17 cells have recently been implicated in the pathogenesis of various types of autoimmune diseases (reviewed in Ref. 55); however, IL-17 deficiency did not significantly impact the severity of EAM (56). Though these gene-ablated mice provided us with much important information, these studies do not necessarily lead to an effective therapy. In this study, we showed that SOCS1 DNA administration inhibited a broad array of cytokine production from CD4+ T cells (Fig. 4B) and effectively reduced myocardial inflammation (Fig. 1). Compared with inhibition of a single cytokine, SOCS1 DNA therapy could be a more useful therapy that inhibits various signaling pathways to induce production of cytokines.

In the current study, SOCS1 DNA administration was efficacious against EAM development, and inhibition of SOCS1 molecules by SOCS1 antagonist DNA administration enhanced the severity of myocarditis. We demonstrated that SOCS1 DNA administration inhibits the stimulation of self-Ag–presenting DCs inducing cardiac myosin-specific CD4+ T cell responses in peripheral compartments in vivo. Given the availability of clinically effective drugs targeting SOCS1, our findings show new therapeutic perspectives for the treatment of autoimmune myocarditis and cardiomyopathy.

**FIGURE 8.** pSOCS1 administration inhibited the development of myocarditis induced by cardiac Ag-loaded BMDC injection but not by heart-specific CD4+ T cells. (A–D) CD4+ T cells were purified from diseased mice and restimulated in vitro with MyHC-α for 48 h before transfer into SCID recipients. pSOCS1, pdnSOCS1, or control plasmid was injected on days 0 and 5 after the transfer. Heart-to-body weight ratios (B; n = 5 mice/group), representative H&E-stained sections of hearts (C), and results of flow cytometry analysis of CD45+ heart infiltrates (D; n = 5 mice/group) of naive and adoptive transferred mice at day 10. Arrowheads indicate infiltrating cells. Scale bar, 50 μm. (E–H) Mice were immunized with activated MyHC-α–or control OVA peptide-pulsed DCs on days 0, 2, and 4. Mice immunized with MyHC-α–pulsed DCs were treated with pSOCS1, pdnSOCS1, or control plasmid on days 0 and 5. Heart-to-body weight ratios (F; n = 6–12 mice/group), representative H&E-stained sections of hearts (G), and results of flow cytometry analysis of CD45+ heart infiltrates (H; n = 5 mice/group) of naive and transferred mice at day 10. Arrowheads indicate infiltrating cells. Scale bar, 50 μm. Data are expressed as means ± SEM. Data are representative of at least two independent experiments. *p < 0.05, **p < 0.01 compared with control.
Acknowledgments
We thank T. Okamura, Y. Shiogama, T. Wada, K. Watanabe, H. Shibata, and M. Namikata for technical support and valuable discussion and F. Miyama of the Medical English Communications Center, University of Tsukuba, for grammatical revision of this manuscript.

The authors have no financial conflicts of interest.

References

Supplementary Figure 1. *Socs1* gene expression in the heart. RNA samples were obtained from EAM hearts on days 0, 14, 21, 28 and 35, and used as a template for QRT-PCR. Results represent the average gene induction in five to six independent heart samples. Results of one of two representative experiments are shown. *P < 0.05 compared to control.
Supplementary Figure 2. Impaired cytokine production by H^+/K^+ ATPase α (H/Kα)-specific CD4^+ T cells in pSOCS1-treated mice. BALB/c mice were immunized twice, on days 0 and 7, with 100 μg of H/Kα p253-277 in an emulsion with CFA and treated with pSOCS1, pdnSOCS1 or control plasmid on days 0, 5 and 10. Splenocytes were isolated from mice on day 14 and cultured in the absence or presence of H/Kα peptide (1 μg/ml) for 72 h. Cytokines and chemokines in the culture supernatants were measured by ELISA. Data are expressed as mean ± SEM from triplicate culture wells. Results of one of two representative experiments are shown. *P < 0.05 compared to H/Kα stimulated control and #P < 0.05 compared to unstimulated control.
Supplementary Figure 3. Impaired cytokine production by OVA-specific CD4+ T cells in pSOCS1-treated mice. BALB/c mice were immunized twice, on days 0 and 7, with 100 μg of OVA p323-339 in an emulsion with alum and treated with pSOCS1, pdnSOCS1 or control plasmid on days 0, 5 and 10. Splenocytes were isolated from mice on day 14 and cultured in the absence or presence of OVA peptide (5 μg/ml) for 72 h. Cytokines and chemokines in the culture supernatants were measured by ELISA. Data are expressed as mean ± SEM from triplicate culture wells. Results of one of two representative experiments are shown. *P < 0.05 compared to OVA stimulated control and #P < 0.05 compared to unstimulated control.
