Resolvin D1 and Aspirin-Triggered Resolvin D1 Promote Resolution of Allergic Airways Responses

Alexandre P. Rogerio,* Oliver Haworth,* Roxanne Croze,* Sungwan F. Oh,† Mohib Uddin,* Troy Carlo,* Michael A. Pfeffer,* Rebekah Priluck,* Charles N. Serhan,† and Bruce D. Levy*†

Asthma is a chronic inflammatory disease of the airways without curative therapy (1). Allergen-induced airway responses are common in asthma and notable for infiltration and accumulation of eosinophils and T lymphocytes in the airways. These leukocytes, as well as lung-resident cells, can produce soluble mediators that promote airway inflammation, mucus metaplasia, and hyperresponsiveness, which are cardinal features of asthma (1). Most patients with asthma have symptoms that are readily controllable by standard asthma therapies, including β2-adrenergic agonists, low doses of inhaled corticosteroids, or leukotriene modifiers (1). However, 5–10% of asthmatic individuals have poorly controlled disease with frequent exacerbations or symptoms that are refractory to current therapy (2).

During inflammation, the essential ω-3 fatty acid docosahexaenoic acid (DHA; C22:6) is available for enzymatic transformation to several anti-inflammatory and proresolving mediators, including D-series resolvins (3). Proresolving mediators are generated from DHA in asthmatic airways (4) and during experimental allergic airway responses (4, 5), and these DHA-derived mediators can promote clearance of eosinophils and T cells (4, 6). Epidemiological evidence has uncovered a significant relationship between dietary fish ingestion and a lower prevalence of allergy and asthma (7), and DHA is enriched in cold-water fish. In addition, DHA is present in airway mucosa, and, in comparison with healthy individuals, mucosal levels of DHA decrease in asthmatic individuals, particularly in relation to the ω-6 fatty acid arachidonic acid (C20:4) (8). Resolvin D1 (RvD1) is enzymatically derived from DHA and has recently been identified to inhibit neutrophil activation (9–11), regulate cytokines (12, 13), and protect after ischemia-reperfusion second organ injury (14, 15) and LPS-induced acute lung injury (16). In this study, we determined the actions of RvD1 and its aspirin-triggered epimer RvD1 (AT-RvD1) on the course and resolution of allergic airway responses in a murine experimental model of asthma.

Materials and Methods

Animals

After approval by the institutional review board of Harvard Medical Area (protocol 03618), 5–7-week-old FVB male mice (body weights 20–25 g; Charles River Laboratories) were housed in isolation cages in pathogen-free conditions on a light–dark cycle with light from 7:00 to 20:00 at 25°C. Mice were fed a standard diet (Laboratory Rodent Diet 5001; PMI Nutrition International) containing 4.5% total fat with 0.26% ω-3 fatty acids and <0.01% C20:4 and were provided water ad libitum.

Marine asthma model

Mice were sensitized by i.p. injection on protocol days 0 and 7 with 10 μg OVA (Grade III; Sigma-Aldrich) plus 1 mg aluminum hydroxide as ad-
juvenile (Sigma-Aldrich) in 0.2 ml saline. On protocol days 14, 15, 16, and 17, mice were aerosol challenged with 6% (w/v) OVA for 25 min (as in Ref. 17). Some mice received RvD1 (10 ng) or vehicle (0.01% (v/v) ethanol) in saline by i.v. injection 1 h before mice were euthanized on protocol day 18 after first sensitization. In a second cohort, mice received RvD1 (1–100 ng) or vehicle (0.1% (v/v) ethanol) alone by i.v. injection on protocol days 18, 19, and 20, and tissue samples were obtained for analyses during the resolution phase of the model on protocol days 21 and/or 25. In a fourth cohort, mice received RvD1 (100 ng), AT-RvD1 (100 ng), or vehicle (0.1% (v/v) ethanol) alone by i.v. injection on protocol days 18, 19, and 20, and tissue samples were analyzed on protocol day 21. Doses were chosen based on prior reports with the E-series resolvin E1 in this model (17) and with RvD1 and AT-RvD1 in murine models of acute inflammation (11). Resolution was quantitated by calculation of the resolution index (time interval from maximum to half-maximum) for bronchoalveolar lavage fluid (BALF) eosinophils (as in Refs. 17, 18).

Bronchoalveolar lavage

BAL was performed with two 1-ml aliquots of PBS with 0.6 mM EDTA. Cells in BALFs were resuspended in PBS and counted using a hemocytometer. Cytospins preparations were done by cytocentrifugation (265 × g; StatSpin), and cells were stained with Wright–Giemsa (Sigma-Aldrich) for quantification of leukocyte subsets; at least 200 cells per slide were counted.

**Histology and immunohistochemistry**

In select animals, lungs were collected, fixed with 10% (v/v) buffered formalin at a perfusion pressure of 20 cm H₂O, and embedded in paraffin for staining with H&E or periodic acid-Schiff (PAS) reagent (Sigma-Aldrich) (as in Ref. 17). Additional sections were immunostained for rabbit anti-mouse ALX/FPFR2 (1:50; Santa Cruz Biotechnology), and developed using the Vectastain Elite ABC kit (Vector Laboratories) and diaminobenzidine (Sigma-Aldrich) as a substrate. National Institutes of Health ImageJ 1.36b imaging software (National Institutes of Health, Bethesda, MD) was used to quantitate ALX/FPFR2 receptor abundance. Scores for peribronchiolar inflammatory cell infiltrates in sections from each lung were graded as in Bilbois et al. (19)—namely, a score of 0 indicated the absence of inflammatory cell infiltrates; a score of 1, less than five layers of inflammatory cells in <50% of the bronchiolar submucosa; 2, more than five layers of inflammatory cells in <50% of the bronchiolar submucosa; 3, more than five layers of inflammatory cells in <50% of the bronchiolar submucosa; and 4, more than five layers of inflammatory cells in >50% of the bronchiolar submucosa (19). To quantitate the level of mucus expression in the airway, the number of PAS staining (PAS⁺) cells in individual bronchioles was counted as described previously (20).

**Measurement of lung resistance**

For measurement of airway hyperresponsiveness, mice were anesthetized with sodium pentobarbital (80 mg/kg, i.p.) and mechanically ventilated with a FlexiVent mouse ventilator (Scireq), and aerosolized methacholine (0.1, 3, 10, 30, and 100 ng/ml) was delivered in-line through the inhalation port for 10 s. Lung resistance was determined as the mean of 10 measurements obtained for each concentration of methacholine and reported as the percent difference from baseline (PBS nebulization). No BAL or histological analysis was performed on mice undergoing measurement of airway hyperresponsiveness.

**Cytokines and lipid mediators**

Samples of cell-free BALF (centrifuged for 10 min at 300 × g) were assigned an individual code, and peptide mediators were measured by bead array (Aushon BioSystems) and lipid mediators by ELISA (leukotriene B₄ [LTB₄]; [Cayman Chemical] and lipoxin A₄ [LXA₄]; [Neogen]).

**Western blots**

Lungs were homogenized with a hand-held glass dounce. Samples were denatured, and equal amounts of protein (50 μg) were loaded per lane prior to electrophoresis with 12% (w/v) SDS-PAGE gels. After transfer onto a polyvinylidene difluoride membrane (0.2 μm pore size) using the Mini-PROTEAN 3 apparatus (Bio-Rad), immunoblots were probed with primary Abs to IsBo (1:1000 dilution; Santa Cruz Biotechnology) followed by a donkey anti-rabbit IgG conjugated to HRP (1:5000 dilution; GE Health-care) and were visualized using ECL (GE Healthcare). An Ab against β-actin (1:500 dilution; Santa Cruz Biotechnology) was used as a loading control. The immunoblotted membranes were detected using a Chemiluminescence Substrate kit (Thermo Scientific) and visualized on the FluoroChem HD2 Imaging System (Alpha Innotech). Densitometric analysis was performed using integrated density analysis provided by AlphaEaseFC software.

**Gene expression**

Lungs were obtained and snap frozen. RNA was extracted with TRIzol (Invitrogen) and reverse transcribed. The cDNA was amplified as a template for the quantification of murine ALX/FPFR2 (GenID: 14289) by real-time PCR using a Stratagene real-time PCR machine (model MX 3005; Stratagene). Fold change was calculated as 2−ΔΔCT for the difference between the cycle threshold (Ct) value for the gene of interest and the respective Ct value for ppi (ΔΔCT) compared with day 0.

**Lung macrophage isolation and allergen clearance**

Macrophages from control or OVA-sensitized and -challenged animals were obtained at protocol day 21 from BAL as described previously (21). Phagocytosis was determined in vitro using AMJ2-C8 (murine alveolar macrophages cell line; American Type Culture Collection) or freshly obtained murine alveolar macrophages (mAlvMacs). As in Ref. (22), cells were placed on coverslips in 96-well plates (2 × 10⁵ cells/well) in media (RPMI 1640 plus 10% FCS containing L-glutamine and antibiotics) and incubated overnight at 37°C. Nonadherent cells were removed, and mAlvMacs were supplemented with fresh medium. Macrophages (cell line or from BAL) were treated with RvD1, AT-RvD1 (0.1, 10, or 100 nM), or vehicle (ethanol <0.01%) and incubated in the dark (20 min, 37°C). Rabbit anti-OVA IgG-Ab–coated polystyrene microsphere beads were prepared according to (the manufacturer’s instructions [Polysciences]) and added to the cells at a ratio of 13 beads/cell. Immediately (time 0) or after 15 min, cells were washed with PBS and paraformaldehyde (4%) was added. After 30 min, cells were washed again with PBS, and FITC-conjugated goat anti-rabbit Ab (1:150) was added (35 min, room temperature, in the dark). Supernatants were removed, and after washing in PBS, the cells on the coverslips were mounted for fluorescent microscopy. Beads were counted in both light and fluorescence images that were acquired for ≥50 cells in each incubation. Because Abs are not membrane permeable, only adherent noninternalized beads are fluorescent. This allows for distinction between internalized and cell-adherent beads. To quantify particle internalization, the number of surface-bound beads was counted from the fluorescence images, and the total number of beads from the nonfluorescent images. The phagocytosis index was determined by subtracting the number of fluorescent beads from the total number of beads (nonfluorescent images) to derive the number of internalized beads. For each cell counted, the number of internalized beads was divided by the total number of beads to derive its phagocytosis index.

**Macrophage phagocytosis of allergen in vivo**

Mice were sensitized to OVA as described above. On protocol day 14, RvD1 (100 ng), AT-RvD1 (100 ng), or vehicle (0.1% [v/v] ethanol) alone was administered i.p. in 100 μl sterile saline (as in Ref. 18). After 5 min, rabbit anti-OVA IgG-Ab–coated beads were injected i.p. The number of beads was ∼13 latex beads per macrophage based on the anticipated total number of macrophages (∼1 × 10⁶) expected from control mice (nonstimulated) (23). A 15 min, peritoneal lavage fluids (2 ml 0.9% saline with 0.6 mM EDTA) were added (4% final concentration) to peritoneal lavage fluids. After 30 min, cells were washed with PBS, and FITC-conjugated goat anti-rabbit Ab (1:150) was added (35 min, room temperature, in the dark). After centrifugation (265 × g, 5 min), the supernatants were removed, and cells were washed in PBS. Cells were mounted for fluorescent microscopy by cyto-spin (265 × g; StatSpin), and the phagocytosis index was calculated as described above.

**RvD1 and AT-RvD1 further metabolism and inactivation**

AMJ2-C8 cells were suspended (2 × 10⁶/ml) in PBS with CaCl₂, MgCl₂, and dextrose (10 mM) and warmed (37°C, 5 min) prior to incubation for 30 min (37°C) in the presence of RvD1, AT-RvD1 (100 nM), or vehicle (ethanol 0.1%). Indomethacin (100 μM; Sigma-Aldrich) was added to select cells just prior to RvD1. Reactions were stopped with 2.5 volumes of iced methanol and stored at −20°C (∼12 h) until extraction. d4-PGE₂ was added as an internal standard to calculate recovery during C18 solid-phase column extraction. The methyl formate eluate was taken for liquid chromatography–tandem mass spectrometry (LC-MS/MS)-based quantita-
tion of RvD1, AT-RvD1, and the RvD1 metabolite 17-oxo-RvD1 (as in Refs. 11, 24). Briefly, metabolism to 17-oxo-RvD1 was determined by monitoring at mass-to-charge ratio (m/z) 373 and the presence of at least three additional prominent daughter ions, including m/z 355 [-H2O]; 337 [-2H2O]; 329 [373-CO2]; 275 [373-CHO-CH2(CH2)2CH3]; 231 [373-CHOH-CH2(CH2)2CH2CO2]; and 141 [CHO-CH2(CH2)2CH2CO2]. The quantities of 17-oxo-RvD1 relative to its precursors (RvD1, AT-RvD1) were expressed as percent conversion to the metabolite.

**Statistical analysis**

Statistical significance was assessed by the Student t test and one-way ANOVA. When significant differences were identified, individual comparisons were subsequently performed with the Tukey’s test. The p values <0.05 were considered significant.

**Results**

**RvD1 counters the development of allergic airway responses**

To determine if RvD1 could regulate allergic airway inflammation, a single dose of RvD1 (10 ng) or vehicle (0.01% ethanol) was given i.v. to animals on protocol day 18 after allergen sensitization and challenge with OVA. Leukocytes in the airways were measured 1 h later in BALFs. Total BALF cells were decreased after i.v. RvD1, with significant decrements in BALF eosinophils and lymphocytes (Fig. 1A). BALF eosinophils were decreased by ~60% from 1.45 ± 0.33 (vehicle) to 0.57 ± 0.10 (RvD1) (mean × 10^6/m) ± SEM for n = 7; p < 0.05), and BALF lymphocytes were also decreased by ~60% from 2.4 ± 0.6 (vehicle) to 0.87 ± 0.2 (RvD1) (mean × 10^6/m) ± SEM for n = 7; p < 0.05). BALF eosinophils were undetectable, and BALF lymphocytes were 0.49 ± 0.22 (mean × 10^6/m) ± SEM for n = 3) (Fig. 1).

To determine if RvD1 could prevent the development of allergic airway responses, 1, 10, or 100 ng or vehicle (0.1% ethanol) was given to sensitized animals i.v. 30 min prior to each daily allergen aerosol challenge for a period of 4 d (see Materials and Methods). RvD1 again led to significant decrements in BALF total cells, in particular eosinophils (Fig. 1B). A total of 10 ng of RvD1 was the most potent dose. Of interest, the magnitude of RvD1’s inhibition at this dosing schedule was similar to a single administration given 1 h prior to BAL (Fig. 1A, 1B). The RvD1 dose-response relationship for inhibition of BALF eosinophils and lymphocyte numbers appeared to be bell-shaped as neither 1 nor 100 ng of RvD1 was more effective than 10 ng. In contrast, RvD1 gave a dose-dependent increase in BALF macrophages (Fig. 1B).

Leukocyte infiltration into the lung parenchyma was markedly decreased by RvD1. Histopathological analyses revealed the RvD1 (10 ng, i.v.) decreased leukocyte accumulation in the peribronchial regions and decreased mucus metaplasia in bronchial epithelial cells (Fig. 2A–C). Cell-free BALFs were analyzed by cytokine bead array and ELISA to determine the impact of i.v. RvD1 on levels of select inflammatory mediators. RvD1 administration led to significantly lower levels of IL-5, ~60% lower than vehicle (Fig. 2D). Levels of IL-4, IL-13, and thymus and activation regulated chemokine (TARC) were also decreased but did not reach statistical significance at this sample size. There was no significant effect of RvD1 on cotaxin, IL-10, IFN-γ, or LXA4. RvD1 (10 ng) significantly reduced lung IsxBα degradation (Fig. 2E). In addition, airway hyperresponsiveness to inhaled methacholine was dampened by RvD1 (10 ng, i.v.), reaching statistical significance only at 100 mg/ml methacholine (Fig. 2F).

RvD1 can interact with ALX/FPR2 receptors to transduce, in part, its counterregulatory actions (9, 10, 25), so the expression of murine ALX/FPR2 receptors in the lung was determined by quantitative PCR and immunohistochemistry. Compared to baseline mice prior to allergen sensitization and challenge (ΔCT 6.37 ± 0.33), lung ALX/FPR2 expression was decreased at both peak inflammation (protocol day 18) (ΔCT 7.05 ± 0.20) and early resolution (protocol day 21) (ΔCT 7.43 ± 0.24; p < 0.05 for n = 3, mean ± SEM). These findings were consistent with a fold change of 0.64 (days 18) and 0.49 (day 21), respectively, in gene expression. Lung immunohistochemistry for ALX/FPR2 abundance gave similar findings as quantitative PCR. Prominent ALX/FPR2 staining was present at baseline in airway epithelial cells and alveolar macrophages and decreased during the allergic airway responses at protocol days 18 and 21 (Fig. 2G, 2H).

**RvD1 and AT-RvD1 enhance the resolution of airway inflammation**

In view of RvD1’s protective actions in the airway, we next determined the influence of RvD1 and its aspirin-triggered 17(R)-epimer (AT-RvD1) on the resolution of established airway inflammation (Fig. 3). After animals were OVA sensitized and aerosol...
challenged, RvD1 (10–100 ng), AT-RvD1 (100 ng), or vehicle (0.1% ethanol) was administered i.v. for 3 consecutive days (protocol days 18–20), and no further allergen challenges were performed (Fig. 3A). BALF leukocytes were enumerated on days 21 and 25. During resolution (day 21), RvD1-treated mice displayed a dose-dependent decrease in total BALF cells with associated changes in eosinophils, macrophages, and lymphocytes (Fig. 3B). Compared to RvD1, an equivalent dose (100 ng) of AT-RvD1 led to even more significant decrements in BALF total cells, eosinophils, and lymphocytes (Fig. 3B). With AT-RvD1, BALF eosinophils decreased from 1.17 ± 0.07 (vehicle) to 0.42 ± 0.08 (AT-RvD1) (mean × 10^6/ml ± SEM for n > 6; p < 0.05). In addition, AT-RvD1 decreased BALF lymphocytes from 2.05 ± 0.52 (vehicle) to 0.67 ± 0.2 (AT-RvD1) (mean × 10^5/ml ± SEM for n > 6; p < 0.05). At day 25, BALF eosinophil and lymphocyte numbers were near baseline. Of interest, AT-RvD1 led to small, but significant, decreases in eosinophils and increases in macrophages at this time point (Fig. 3B).

The resolution interval is defined as the time required for cell numbers to decrease to 50% of the maximum at peak inflammation (18), and in vehicle-exposed mice, the endogenous resolution interval for BALF eosinophils was ∼4.5 d (Fig. 3C, 3D). RvD1-treated mice displayed a modestly decreased resolution interval (∼4 d for 100 ng) (Fig. 3C). Of note, the resolution interval for BALF eosinophils was markedly decreased with AT-RvD1 to ∼2 d to ∼45% of the resolution interval with vehicle (Fig. 3D), indicative of more rapid resolution of acute allergic inflammation.

To determine the impact of airway delivery, mice were given daily intranasal RvD1 (100 ng), AT-RvD1 (100 ng), or vehicle (0.5% ethanol) on protocol days 18–20. Exposure to AT-RvD1, but not RvD1, at this dose led to significant decreases in BALF eosinophils at day 21 (Fig. 3E). BALF eosinophils decreased from 1.86 ± 0.27 (vehicle) to 0.83 ± 0.15 (AT-RvD1) (mean × 10^6/ml ± SEM for n > 5; p < 0.05). Intranasal AT-RvD1 also increased BALF macrophages and lymphocytes. Overall, significant differ-
ences were not obtained for changes in total BALF cell numbers (Fig. 3E).

AT-RvD1 accelerates the resolution of lung inflammation and airway mucus metaplasia and hyperresponsiveness

The proresolving actions of AT-RvD1 for airway leukocytes were also evident for lung inflammation and airway mucus metaplasia and hyperresponsiveness. AT-RvD1 was more potent than RvD1 for each of these metrics (Fig. 4). Lung histopathology demonstrated that AT-RvD1 facilitated the resolution of leukocyte infiltration with less reactive bronchial epithelial cells and mucus metaplasia, as detected by H&E and PAS staining, respectively (Fig. 4A, 4B). These changes were quantitated by determining an inflammation score (see Materials and Methods) and enumerating the numbers of PAS+ cells in the airways, both of which were significantly reduced with AT-RvD1 (Fig. 4B). In addition, mice treated with AT-RvD1 displayed significant protection from methacholine-induced increases in mean lung resistance (Fig. 4C). Thus, AT-RvD1 gave potent proresolving actions for allergic airway responses.

AT-RvD1 treatment regulates airway mediators

To uncover proresolving mechanisms, BALF levels of peptide and lipid mediators were measured during early resolution (protocol day 21). Exposure to both RvD1 and AT-RvD1 led to significantly decreased levels of IL-17, LTB₄, and TGF-β (Fig. 5A–C). AT-RvD1 alone led to significant decrements in eotaxin and TARC (Fig. 5D, 5E), and RvD1 gave significant regulation of IL-5 and IL-23 (Fig. 5F, 5G). AT-RvD1 also decreased both of these mediators, but the results did not reach statistical significance at this sample size. No significant changes were observed in IL-10, MIP-1α, IL-13, IL-4, or IFN-γ (Fig. 5H–L). Because RvD1 regulates specific miRNAs to decrease NF-κB signaling in acute inflammation (12), and RvD1 downregulated IKKα degradation to prevent the development of allergic responses (Fig. 2E), the impact of AT-RvD1 and RvD1 on this measure of NF-κB pathway activation was next determined during resolution. In contrast to their administration during induction of the airway inflammation, neither AT-RvD1 nor RvD1 led to significant changes in IKKα degradation at this resolution time point (Fig. 5M).

RvD1 is metabolized by alveolar macrophages

Recombinant eicosanoid oxidoreductase and murine lung rapidly converts RvD1 to an inactive 17-oxo-RvD1 metabolite, and AT-RvD1 resists this rapid inactivation (11). Because the in vitro and in vivo results with AT-RvD1 were more potent than RvD1, the metabolism of these compounds was next determined with a murine alveolar macrophage cell line (AMJ2-C8). Cells were ex-
posed (30 min, 37˚C) in vitro to either RvD1 or AT-RvD1. Lipids were extracted and taken to LC-MS/MS for analyses of RvD1 and AT-RvD1 metabolism (see Materials and Methods). In parallel, some cells incubated with RvD1 were also exposed to indomethacin, which inhibits the eicosanoid oxidoreductase (25), an enzyme that is highly expressed in the lung (26) and capable of converting the alcohol at carbon 17 position to a ketone (9) (Fig. 6A). Metabolic inactivation of AT-RvD1 by the mAlvMacs was significantly decreased relative to RvD1 (63.8 ± 7.5% with AT-RvD1 versus RvD1, mean ± SEM for n = 3; p < 0.05). Indomethacin also decreased RvD1 inactivation by ~25% (Fig. 6B).

**FIGURE 4.** Impact of RvD1 and AT-RvD1 on the resolution of airway inflammation, mucus, and hyperreactivity. (A) Lung tissue sections were obtained at protocol day 21 from mice given RvD1 (100 ng), AT-RvD1 (100 ng), or vehicle and stained with H&E (original magnification ×200) or PAS reagent (original magnification ×400) (see Materials and Methods). Arrows indicate examples of mucus-containing (magenta) goblet cells. (B) Quantitative analyses of lung inflammation and bronchial PAS-positive cells in lung sections were performed (see Materials and Methods). (C) Airway hyperresponsiveness to aerosolized methacholine was assessed on day 21 by measuring the mean lung resistance (percent of baseline) (see Materials and Methods). Results represent the mean ± SEM for two or more independent experiments with three or more mice per group per experiment. *p < 0.05 versus vehicle. Br, Bronchus.

**FIGURE 5.** RvD1 and AT-RvD1 selectively regulate inflammatory mediators during resolution of allergic inflammation. (A–L) BALF levels of peptide and lipid mediators were measured in OVA-naive, nonallergic control mice (white) and on protocol day 21 in materials obtained from mice given RvD1 (100 ng; gray), AT-RvD1 (100 ng; black), or vehicle (hatched) (see Materials and Methods). (M) Lung tissue was obtained on protocol day 21 during resolution and was subjected to Western blotting analyses for IkBα (see Materials and Methods). Results represent the mean ± SEM for two or more independent experiments with three or more mice per group per experiment. *p < 0.05 versus vehicle. nd, Not detected.

**AT-RvD1 enhances macrophage clearance of allergen by phagocytosis**

Because AT-RvD1 increased BALF macrophages in vivo during resolution (Fig. 3), and macrophages play important proresolving roles in clearing inflamed tissues (24), the impact of AT-RvD1 and RvD1 on macrophage phagocytosis of allergen was determined. AMJ2-C8 cells (in vitro) and mAlvMacs that were isolated from BALF on protocol day 21 from control animals or mice that were OVA sensitized and aerosol challenged (ex vivo) were exposed to IgG-OVA coated beads (see Materials and Methods; Fig. 6C). In
The Journal of Immunology

FIGURE 6. AT-RvD1 resists metabolic inactivation by macrophages and stimulates macrophage clearance of allergen. mAlvMac cells (AMJ2-C8) were incubated (30 min, 37°C) in the presence of RvD1 (in some cases with indomethacin) or AT-RvD1. Lipids were extracted, and RvD1 metabolites were identified and quantitated by LC-MS/MS analyses (A) (see Materials and Methods). (B) Values are expressed as the relative percent 17-oxo-RvD1 metabolite relative to the total starting compound. (C) Macrophage phagocytosis of allergen was determined using rabbit anti-OVA IgG-coated beads (2 μm) that are detectable by light microscopy. In nonpermeabilized cells, a fluorophore-tagged Ab (FITC-conjugated goat anti-rabbit Ab) was used to distinguish adherent (fluorescent) from internalized (nonfluorescent) beads (original magnification ×1000). A phagocytosis index was calculated after 15 min in the presence of RvD1, AT-RvD1 (0.1, 10, and/or 100 nM), vehicle (V), or media alone (M) using AMJ2-C8 cells in vitro (D) or mAlvMacs (E, F) ex vivo that were isolated from BALF of control (E) or OVA-sensitized and -challenged (F) mice (protocol day 21) (see Materials and Methods). The dashed black line indicates the baseline phagocytosis index. (G) The phagocytosis index was determined in vivo in OVA-sensitized or control mice 15 min after i.p. injection of OVA IgG-coated beads. In some animals, RvD1 (100 ng), AT-RvD1 (100 ng), or vehicle (0.1% ethanol) were given i.p. 5 min before introduction of the beads. Results represent the mean ± SEM for two or more independent experiments. *p < 0.05 versus vehicle, †p < 0.05 versus RvD1.

the nanomolar range, AT-RvD1 increased the macrophage phagocytosis index within 15 min (37°C) for allergen-coated beads (Fig. 6D–G). The increased phagocytosis index was concentration dependent for AT-RvD1 with AMJ2-C8 cells (Fig. 6D). AT-RvD1 also increased the allergen phagocytosis index for mAlvMacs from control and OVA-allergic mice (Fig. 6E, 6F). It was not feasible to deliver the OVA-coated beads to alveoli in live animals, so the in vivo allergen phagocytosis index was determined for peritoneal macrophages in OVA-sensitized mice. AT-RvD1 also significantly increased this proresolving functional response in vivo.

Discussion

In this study, we have provided evidence for both anti-inflammatory and proresolving actions for RvD1 and its epimer AT-RvD1 in allergic airway responses. When given to OVA-sensitized and aerosol-challenged mice, RvD1 reduced the development of allergic airway responses. RvD1 most potently regulated eosinophilia with decreases in levels of IL-5, an important Th2 cytokine that serves as a chemoattractant and activator of eosinophils. BALF levels of the related Th2 cytokines IL-4 and IL-13 were also decreased, and IL-33 in the lung was significantly increased by RvD1, suggesting decreased activation of NF-kB. RvD1 also reduced bronchial mucus metaplasia with a more modest effect on airway hyperresponsiveness to methacholine. Levels of the counterregulatory mediators IL-10 and LXA4 were not increased, indicating nonredundant anti-inflammatory signaling circuits for RvD1.

To determine if these anti-inflammatory properties for RvD1 would also enhance the resolution of allergic airway responses, RvD1 was given after allergen sensitization and challenge was complete. RvD1 led to significant decrements in allergic lung inflammation 1 h after administration and during early resolution, leading to an ~10% decrease in the eosinophil resolution interval. An equivalent dose of AT-RvD1 (100 ng, ~0.005 mg/kg) provided significantly greater proresolving actions, decreasing the eosinophil resolution interval by >50%, an approximate doubling of the pace of resolution relative to RvD1. Both AT-RvD1 and RvD1 can serve as an agonist at ALX/FPR2 receptors to transduce, in part, their proresolving actions (9, 10, 25, 27). ALX/FPR2 was broadly expressed in airway epithelial cells and alveolar macrophages and dynamically regulated during allergic airway responses that led to decreased receptor abundance. These changes are similar to those observed in human asthma (28). In addition to regulation of ALX/FPR2 receptors, proresolving signaling can also be decreased by metabolic inactivation of RvD1 and AT-RvD1 (11). Although enzymatically generated from DHA by distinct biosynthetic pathways, RvD1 and AT-RvD1 are diastereomers, differing only in stereochemistry at carbon 17 (reviewed in Ref. 29). This change in stereochemistry for AT-RvD1 provides a significant increase in the compound’s t1/2 in vivo, secondary to resistance to metabolic inactivation by eicosanoid oxidoreductases (11, 25). In this study, AT-RvD1 had a decreased rate of metabolic inactivation relative to RvD1, which likely contributed to AT-RvD1’s enhanced in vitro and in vivo pharmacological actions. In addition, the reduced ef-
ficacy of airway administration relative to the i.v. route was notable given the capacity for lung macrophages to inactivate both RvD1 and AT-RvD1.

During resolution, AT-RvD1 led to significant decrements in select inflammatory mediators, namely BALF IL-17, eotaxin, TARC, TGF-β, and LTβ4. Unlike when given prior to aerosol challenge, neither RvD1 nor AT-RvD1 significantly changed lung Irxβα during resolution. In the setting of allergen-driven inflammation, inhaled allergen needs to be cleared to facilitate resolution. AT-RvD1 increased alveolar macrophage phagocytosis of allergen-coated beads in vitro in a concentration-dependent manner, and AT-RvD1 increased the peritoneal macrophage allergen phagocytosis index in vivo. Alveolar and peritoneal macrophages differ in several respects, in particular their uptake of particulate and soluble Ag that is spatiotemporally regulated in the airway (30–32). Because of safety concerns delivering the beads directly into the airway and the animals had been systemically sensitized by i.p. injection, peritoneal macrophages were chosen for in vivo analysis. A potential caveat to our findings is that the increased phagocytic capacity of peritoneal relative to alveolar macrophages may overestimate the role of lung macrophages in vivo in the clearance of allergen delivered directly into the respiratory tract; however, AT-RvD1 promoted increased allergen engulfment by both peritoneal macrophages in vivo and alveolar macrophages in vitro. Together, these results point to more rapid allergen clearance by AT-RvD1–exposed macrophages as a proresolving mechanism for allergic airway responses, including airway inflammation, mucus metaplasia, and hyperresponsiveness to methacholine.

The development of airway inflammation in asthma is characterized by leukocyte accumulation and in many individuals is notable for a Th2 cytokine gene expression signature (33). Among the inflammatory mediators implicated in eosinophil recruitment are the Th2 cytokine IL-5 and eotaxin (2). In addition, NF-κB activation plays an essential role in the development of airway eosinophilia in this model of asthma (34). LTβ4 can also serve as an eosinophil chemotactrant, as LTβ4 receptor (BLT1)-deficient mice do not develop eosinophilic inflammation or airway hyperresponsiveness in an experimental asthma model (35). In this study, we have identified RvD1 and AT-RvD1 as potent regulators of murine IL-5, eotaxin, and LTβ4 and eosinophil accumulation after allergen challenge. Eosinophils are a significant source of the IL-17, not Th2 cytokines (17). This is in sharp contrast to the resolution of allergic airway responses (i.e., decreased Th2 cytokines and NF-κB) and in promoting their resolution (i.e., regulation of IL-23 and IL-17 and increased allergen clearance).

In conclusion, these results demonstrate protective anti-inflammatory and proresolving actions for D-series resolvins in airway inflammation. RvD1 and AT-RvD1 decreased eosinophil recruitment and activation, Th2 cytokines early and Th17 cytokines late, airway mucus metaplasia, and airway hyperreactivity to methacholine, and AT-RvD1 promoted the resolution of allergic airway responses by enhancing allergen clearance. Together, these results point to D-series resolvins as a candidate therapeutic modality in allergic disorders and provide a window into potential mechanisms for the association between changes in airway mucosal α3-fatty acids and asthma.
