CCL3 Production by Microglial Cells Modulates Disease Severity in Murine Models of Retinal Degeneration

Hideo Kohno,*† Tadao Maeda,*† Lindsay Perusek,‡ Eric Pearlman,‡ and Akiko Maeda*†

Many degenerative retinal diseases illustrate retinal inflammatory changes that include infiltration of microglia and macrophages into the subretinal space. In this study, we examined the role of chemokines in the Aboca4−/−Rdh8−/− mouse model of Stargardt disease and the Mertk−/− mouse model of retinitis pigmentosa. PCR array analysis of 84 chemokines and related molecules revealed 84.6-fold elevated expression of Ccl3 (MIP-1α) 24 h after light exposure in Aboca4−/−Rdh8−/− mice. Only MIP-1 chemokines, including Ccl3 and Ccl4, displayed peak expression 24 h after light exposure, and peaked earlier than the other chemokines. Secretion of Ccl3 was documented only in microglia, whereas both microglia and retinal pigment epithelium cells produced Ccl2. Exposure of Cx3CR1ΔAAbca4−/−Rdh8−/− mice to intense light resulted in the appearance of Cx3Cr1GFP+ monocytes in the subretinal space. To address the in vivo role of CCL3 in retinal degeneration, Ccl3−/−Abca4−/−Rdh8−/− mice and Ccl3−/−Mertk−/− mice were generated. Following intense light exposure, Ccl3−/−Abca4−/−Rdh8−/− mice displayed persistent retinal inflammation with appearance of Iba-1+ cells in the subretinal space, severe photoreceptor cell death, and increased Ccl4 expression compared with Aboca4−/−Rdh8−/− mice. In contrast, Ccl3−/−Abca4−/−Rdh8−/− mice exhibited a milder retinal inflammation and degeneration than Aboca4−/−Rdh8−/− mice did in age-related chronic retinal degeneration under room light conditions. The deficiency of Ccl3 also attenuated the severity of retinal degeneration in Mertk−/− mice. Taken together, our results indicate that Ccl3 has an essential role in regulating the severity of retinal inflammation and degeneration in these mouse models. The Journal of Immunology, 2014, 192: 000–000.

Clinical and experimental evidence suggests an important role for inflammation in retinal degeneration (1–4). Microglial cells are resident macrophages in the CNS and play a key role in this pathologic inflammatory process (2). Therefore, elucidating the activities and functions of these inflammatory cells is essential in expanding our knowledge of the pathologic of retinal degeneration. Understanding the role of chemokines in retinal degeneration is particularly important because they not only dictate the migration of inflammatory cells, they are also potential drivers of retinal degenerative conditions in humans and mice (5, 6).

The visual process is initiated in photoreceptors by activation of rhodopsin through the photosensitization of visual chromophore 11-cis-retinal to all-trans-retinal. This isomeric conversion initiates a signaling cascade that ultimately propagates the visual stimulus to the brain. To maintain vision, all-trans-retinal is recycled for regeneration of 11-cis-retinal via the visual cycle, which is a series of biochemical reactions in photoreceptors and in retinal pigment epithelial (RPE) cells (7, 8). Although all-trans-retinal is an essential source for regeneration of rhodopsin, delayed clearance of all-trans-retinal is closely associated with retinal disorders (9–11). Clearance of all-trans-retinal in photoreceptors occurs in two steps: translocation of all-trans-retinal from the inside to the outside of photoreceptor outer segment (POS) discs by the ATP-binding cassette transporter 4 (ABCA4) (12) and reduction of all-trans-retinal to all-trans-retinol in the cytosolic lumen of photoreceptor outer segments by retinol dehydrogenase 8 (RDH8) (13, 14). We previously developed a model of retinal degeneration in mice mediated by all-trans-retinal in which Aboca4 and Rdh8 are deleted (15, 16). This model reproduces many features of human Stargardt- and AMD-like retinal phenotype characterized by lipofuscin accumulation, drusen formation, complement activation, photoreceptor/RPE atrophy, and choroidal neovascularization (16). The uniqueness of this model is that the Aboca4−/−Rdh8−/− mouse not only displays age-related chronic degeneration under room light conditions, but also displays acute retinal degeneration when exposed to intense light (15). Our previous study showed that Aboca4−/−Rdh8−/− mice exposed to intense light exhibited increases in several proinflammatory molecules (2). However, these increases were transient, and all inflammatory molecules returned to the basal level 7 d after light exposure. Proinflammatory molecules increased in age-related chronic degenerated retinas of Aboca4−/−Rdh8−/− mice, but many anti-inflammatory molecules were also shown to increase in these mice. These anti-inflammatory molecules included: complement factor H, a regulator of the complement cascade, Arginine liver (ARG1), a marker of M2 macrophages which possesses anti-inflammatory properties (17), and TGF, β 1 (TGFβ), a regulator of the immune cascade. These

findings point to the paradoxical nature of the inflammatory response in Abca4<sup>-/-</sup> Rdh8<sup>-/-</sup> mice.

In this study, we present data indicating that CCL3 is a critical regulator of retinal inflammation, which is associated with severity of retinal degeneration.

Materials and Methods

**Animals**

Abca4<sup>-/-</sup> Rdh8<sup>-/-</sup> mice were generated as described previously, and all mice were genotyped as described previously (16). Only mice with the leucine variation at aa 450 of RPE65 were used. Rdh8 mutation on Cba1 gene was also assessed (18) and only mice without this mutation were used in this study. Ccl2<sup>-/-</sup>, Ccl2<sup>+/+</sup>, Merk<sup>-/-</sup>, and Cx3cr1<sup>-/-</sup> mice were obtained from The Jackson Laboratory (Bar Harbor, ME). Genotyping for Ccl2 was performed with primers; for wild type forward; 5'-ATGAAGCTGTCACACTGTC-3', reverse; 5'-GTGCAAGATGAGTGGG-3', for mutant forward; 5'-TTAAGACGATGCTCCAGACT-3' and reverse, 5'-CAAGAGCTGCTGGTTTCAA-3' (19). Genotyping for Ccl2 was performed with primers; for wild type forward; 5'-TGACAGTCCCCAGTAGC-3', reverse; 5'-TGTTTCAAA-3', for mutant forward; 5'-TGACAGTCCCCAGTAGC-3', reverse; 5'-CAAGAGCTGCTGGTTTCAA-3'.

**Isolation of primary RPE and retinal microglial cells**

Primary mouse RPE cells and retinal microglial cells were prepared from 2-week-old mice. Enucleated eyes were incubated with 2% disperse (Invitrogen) in DMEM (Invitrogen) for 1 h at 37°C, and neural retinas and eyecups were separated under a surgical microscope (ILLUMIN-i; Endure Medical, Cumming, GA). The RPE layer was peeled from eyecups, passed through 40-μm nylon mesh filters (Falcon Plastics, Brooks, SD), and cultured in DMEM containing MEM nonessential amino acids (Invitrogen), penicillin–streptomycin (Invitrogen), 20 mM HEPES, pH 7.0, and 10% FBS. To enrich microglial cells, neural retinas were homogenized and cultured in DMEM containing MEM nonessential amino acids (Invitrogen), penicillin–streptomycin (Invitrogen), 20 mM HEPES, pH 7.0, and 10% FBS for 7 d at 37°C. Adherent cells to the plastic surface were treated with 0.05% trypsin (Invitrogen), and nonadhesive cells were collected as microglial cells.

**ELISA**

Production of Ccl2 and Ccl3 from retinal primary cells was quantified by ELISA kits (Ccl2; MRE00 and Ccl3; MMB00) purchased from R&D systems (Minnesota, MN) with 50 μl of cell culture supernatants of primary RPE or microglial cells. Concentrated cell lysates were prepared with NP-40 lysis buffer containing 20 mM Tris, pH 8.0, 137 mM NaCl, 10% glycerol, and 1% NP-40. Then protein concentration was measured with a BCA protein assay kit (Pierce, Rockford, IL). Production of Ccl3, Ccl4, and IL-1β was also quantified by ELISA kits from R&D systems (Ccl4; MMB00 and IL-1β; MLB00C) with mouse eyes. Two eyes from one mouse were homogenized in 500 μl of PBS with protease inhibitor cocktails (Roche) by a glass-glass homogenizer. The homogenates (50 μl) were used for the quantification. A single data point was obtained from each mouse (2 eyes).

**Fundus fluorescein angiography**

Fluorescein Sodium (ANGIOFLUOR; Alliance Pharmaceuticals, Richmond, TX) was diluted in PBS to 25 mg/ml and injected 2.5 mg per 100 μl per mouse via i.p. injection 10 min prior to taking images, Fundus fluorescein angiography was performed by HRAII (Heidelberg Engineering).

**Quantitative RT-PCR**

All procedures for quantitative RT-PCR were described previously (2). For all procedures to make sections for immunohistochemistry (IHC) and light microscopy were performed as described previously (14). The following Abs were used for IHC: rabbit anti-Ibal Ab (1:400, Wako, Chuo-ku, Osaka, Japan), rabbit anti-Glial Fibrillary Acidic Protein Ab (GPAP; 1:400, Dako, Carpenteria, CA), mouse anti–chondropin 1D4 Ab (1:100, gift from Dr. Robert Molday, University of British Columbia, Vancouver, Canada), anti–T cell Ab (anti-CD3; 1: 200, Dako), anti–CD45 Ab (1:200, Abcam, Cambridge, MA), monoclonal anti–mouse neutrophil Ab (NIM-P14; 1:200, Abcam) and Alexa 488–conjugated peanut agglutinin (PNA; 1:200, Invitrogen). Images of IHC were captured by a confocal microscope (LSM, Carl Zeiss, Thornwood, NY).

**Scanning laser ophthalmoscopy imaging and ultra-high-resolution spectral domain optical coherence tomography**

HRAII (Heidelberg Engineering, Heidelberg,Germany) for scanning laser ophthalmoscopy (SLO) and ultra-high resolution spectral domain optical coherence tomography (SD-OCT; Bioptigen, Research Triangle Park, NC) were used for in vivo imaging of mouse retinas. Mice were anesthetized by i.p. injection of a mixture (20 μl/g body weight) containing ketamine (6 mg/ml) and xylazine (0.44 mg/ml) in 10 mM sodium phosphate, pH 7.2, with 100 mM NaCl. Pupils were dilated with a mixture of 0.5% tropicamide and 0.5% phenylephrine hydrochloride (Midorin-P, Santen Pharmaceutical). Five pictures acquired in the B-scan mode were used to construct each final averaged SD-OCT image. SD-OCT images were scored using our previously established scoring system (20).

**Isolation of light damage**

Mice were dark-adapted for 48 h before exposure to light. Light damage was induced by exposing mice to 10,000 lx of diffuse white fluorescent light (150 W spiral lamp; Commercial Electric, Cleveland, OH) for 30 or 15 min. Before such light exposure, pupils of mice were dilated with a mixture of 0.5% tropicamide and 0.5% phenylephrine hydrochloride (Midorin-P, Santen Pharmaceutical, Osaka, Japan), and after exposure animals were kept in the dark until evaluation.

**Histological analysis**

All procedures to make sections for immunohistochemistry (IHC) and light microscopy were performed as described previously (14). Before such light exposure, pupils of mice were dilated with a mixture of 0.5% tropicamide and 0.5% phenylephrine hydrochloride (Midorin-P, Santen Pharmaceutical, Osaka, Japan), and after exposure animals were kept in the dark until evaluation.

**Quantitative RT-PCR**

All procedures for quantitative RT-PCR were described previously (2). For all procedures to make sections for immunohistochemistry (IHC) and light microscopy were performed as described previously (14). The following Abs were used for IHC: rabbit anti-Ibal Ab (1:400, Wako, Chuo-ku, Osaka, Japan), rabbit anti-Glial Fibrillary Acidic Protein Ab (GPAP; 1:400, Dako, Carpenteria, CA), mouse anti–chondropin 1D4 Ab (1:100, gift from Dr. Robert Molday, University of British Columbia, Vancouver, Canada), anti–T cell Ab (anti-CD3; 1: 200, Dako), anti–CD45 Ab (1:200, Abcam, Cambridge, MA), monoclonal anti–mouse neutrophil Ab (NIM-P14; 1:200, Abcam) and Alexa 488–conjugated peanut agglutinin (PNA; 1:200, Invitrogen). Images of IHC were captured by a confocal microscope (LSM, Carl Zeiss, Thornwood, NY).

**Flat-mount RPE, preparation for immunostaining**

All procedures to make flat-mount RPE were described previously (2). Rabbit anti-ZO-1 Ab (1:200, Invitrogen) was used. Size of RPE cells was measured by LSM image browser (Carl Zeiss, Thornwood, NY).

**Scanning laser ophthalmoscopy imaging and ultra-high-resolution spectral domain optical coherence tomography**

HRAII (Heidelberg Engineering, Heidelberg,Germany) for scanning laser ophthalmoscopy (SLO) and ultra-high resolution spectral domain optical coherence tomography (SD-OCT; Bioptigen, Research Triangle Park, NC) were used for in vivo imaging of mouse retinas. Mice were anesthetized by i.p. injection of a mixture (20 μl/g body weight) containing ketamine (6 mg/ml) and xylazine (0.44 mg/ml) in 10 mM sodium phosphate, pH 7.2, with 100 mM NaCl. Pupils were dilated with a mixture of 0.5% tropicamide and 0.5% phenylephrine hydrochloride (Midorin-P, Santen Pharmaceutical). Five pictures acquired in the B-scan mode were used to construct each final averaged SD-OCT image. SD-OCT images were scored using our previously established scoring system (20).
**Data analysis**

Data representing the means ± SD for the results of at least three independent experiments were compared by the one-way ANOVA test.

**Results**

*Abca4* expression shows the greatest increase in the retina of light exposed *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice

To investigate the involvement of chemokines in light induced acute retinal degeneration of *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice, PCR array analysis for 84 different chemokines and related molecules was performed (Table I). Retinas were harvested from *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> and WT mice 24 h and 7 d after light exposure at 10,000 lx for 30 min. Expression levels of dark adapted *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> and WT mice were used as a basal control for light exposed *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> and WT mice, respectively. Ccl2, Ccl3, Ccl4, Ccl12, and Cxcl10 expression increased 10-fold or higher in light exposed *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice when compared with dark-adapted mice. *Ccl3* expression at 24 h showed an 84.6-fold increase as the greatest change of all tested genes. Only *Cxcl10* increased 10-fold or higher in light exposed WT mice.

Expression of MIP-1 genes peaks earlier than others do after light treatment in *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice

To understand the dynamic nature of the expression of these inflammatory markers that showed 10-fold or higher changes, a time course measurement was conducted. The time course analyses using quantitative PCR for chemokines and chemokine receptors (Fig. 1) revealed that only MIP-1 transcripts, including Ccl3 and Ccl4, peaked 24 h after light exposure in *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice. In contrast, Ccl2, Cxcl10, and Ccl12 had a different temporal profile, which peaked 3 d after light treatment. Light-exposed WT mice did not show a significant increase in these chemokines at either 24 h or 3 d after light exposure. Chemokine receptors were also investigated to determine any changes in expression levels. Ccr1, which is a receptor for Ccl3 and Ccr2, which is a receptor of Ccl2 and Ccl12, peaked 3 d after light exposure in *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice. Ccr5, a receptor for Ccl3 and Ccl4 peaked 12 h and continuously increased until 3 d after light exposure in *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice.

To determine the likely source of Ccl3 and Ccl2 in the retina, primary cultured RPE cells and microglia were isolated from 2-wk-old *Abca4*<sup>−/−</sup>*Rdh8*<sup>−/−</sup> mice (2) and coincubated with POS, which activate microglia/macrophages via TLR4 (2), LPS, a ligand of TLR1/2. Protein amounts of

Fold changes greater than 3 compared with data obtained from dark adapted mice are presented. The data were normalized to the housekeeping genes (Gusb and Gapdh, Actb, Hprt1, and Hsp90ab1). Fold changes greater than 10 are presented in bold text. Minus signs (−) indicate reduced expression.

* Mice were exposed to 10,000 lx white light for 30 min after 48 h of dark adaptation. Before such light exposure, pupils of mice were dilated. Mice were kept in the dark until evaluations.

* RNA was purified from 16 retinas of 4-wk-old mice.
Ccl3 and Ccl2 from these cells were measured by ELISA. Only primary microglia revealed an increase in Ccl3 secretion (Supplemental Fig. 1), whereas both primary RPE and microglial cells increased their Ccl2 secretion, indicating that microglia and monocytes are the dominant cells producing Ccl3 rather than RPE.

Low-grade chronic inflammation in retinas of Abca4−/−Rdh8−/− mice

Given the different gene expression patterns of these factors in the retina, we sought to determine whether they have distinct roles in acute versus chronic retinal degeneration in Abca4−/−Rdh8−/− mice (16). Expression levels of the chemokine and chemokine receptor transcripts were examined in 4-wk-, 6-mo- and 12-mo-old Abca4−/−Rdh8−/− mice and WT mice to assess the changes associated with chronic degeneration of the retina under room light conditions (Fig. 2). Compared with 4-wk-old mice, expression of MIP−1−related genes, including Ccl3, Ccl4, and Ccr1, was increased at the mRNA level in 6-mo-old and decreased in 12-mo-old Abca4−/−Rdh8−/− mice, although Ccr5, which is also a receptor of Ccl3 and Ccl4, was increased until 12 mo old. In contrast, MCP−related genes, including Ccl2 and Ccl12, were increased at 12 mo of age. Ccr2, a receptor of the Ccl2 ligand, was also increased at age of 6 and 12 mo. Cxcl10 displayed a similar expression pattern as MIP−1 genes. These data indicate the presence of low-grade chronic inflammation in the retina of aged Abca4−/−Rdh8−/− mice as observed in human degenerative retinal diseases (1).

Delayed clearance of subretinal microglia in Ccl3−/−Abca4−/−Rdh8−/− mice compared with Abca4−/−Rdh8−/− mice

Because of the distinct expression pattern of MIP−1 genes, Ccl3 and Ccl4, and other chemokines, we hypothesized that MIP−1 gene products have a distinct role in all-trans-retinal mediated retinal degeneration. To test this hypothesis directly, Ccl3−/−Abca4−/−Rdh8−/− mice were generated by crossing Abca4−/−Rdh8−/− with Ccl3−/− mice. Littermate controls were also generated from this mouse cross. To examine the role of CCL3 in acute retinal degeneration, Ccl3−/−Abca4−/−Rdh8−/−, Abca4−/−Rdh8−/−, and WT mice were exposed to 10,000 lx light for 30 min. This light exposure caused more autofluorescent (AF) spots, which was detected by in vivo SLO, which provides a high-quality images by acquiring florescent signals of the retina with a horizontal–confocal view (21) (Fig. 3A). We found significantly more AF spots in Ccl3−/−Abca4−/−Rdh8−/− mice when compared with Abca4−/−Rdh8−/− mice 14 and 21 d after light exposure. In comparison, Ccl3−/− mice did not develop retinal degeneration by the same light exposure condition as Abca4−/−Rdh8−/− mice, and displayed similar resistance to light induced damage as WT mice (Supplemental Fig. 2).

FIGURE 1. Distinct profiles in expression of Ccl3 and Ccl2 in the retina of Abca4−/−Rdh8−/− mice after light exposure. Quantitative RT-PCR was performed with RNA purified from 16 retinas of 4-wk-old Abca4−/−Rdh8−/− and WT mice at each time point. Fold changes in expression to unexposed Abca4−/−Rdh8−/− or WT mice are presented. The expression of each gene was normalized to the housekeeping gene Gapdh. Error bars indicate SD of the means (n = 3). *p < 0.05 versus unexposed Abca4−/−Rdh8−/− mice, †p < 0.05 versus no light exposed WT mice.

FIGURE 2. Low-grade, chronic inflammation in Abca4−/−Rdh8−/− mice. Quantitative RT-PCR was performed with RNA purified from 16 retinas of 4-wk-old, 6-mo-old, and 12-mo-old Abca4−/−Rdh8−/− and WT mice. The expression of genes in Abca4−/−Rdh8−/− mice was compared with WT mice after normalization to the housekeeping gene Gapdh, and presented by fold changes. Error bars indicate SD of the means (n = 3). *p < 0.05 versus 4-wk-old mice.
FIGURE 3. Extended appearance of microglia/macrophage in the subretinal space in Cc3−/− Abca4−/− Rhd8−/− mice after light exposure. Cc3−/− Abca4−/− Rhd8−/−, Abca4−/− Rhd8−/−, and WT mice at 4–6 wk old were exposed to 10,000 lx light for 30 min. (A) Retinal images were captured by in vivo SLO. Images were taken at 7, 14, and 21 d after light exposure (left). Scale bars, 100 μm. Numbers of autofluorescent (AF) spots of each image were counted (right). Error bars indicate SD of the means (n > 6).p < 0.05 versus light-exposed Abca4−/− Rhd8−/− mice. (B) RPE flat-mounts of Abca4−/− Rhd8−/− mice were prepared 7 d after light exposure and stained with anti–Iba-1 (left) and anti-F4/80 (right) Abs. Lower panels show magnified images. (C) SLO image (left) and flat-mount IHC with anti–Iba-1 Ab (right) in the same magnification is presented. Abca4−/− Rhd8−/− mice were exposed to 10,000 lx light for 30 min and kept in the dark for 7 d. Numbers of AF spots in SLO images (per image) and Iba-1+ cells in IHC in the same size area were counted (right graph). ONH is circled by broken line. (D) Retinal cross section of Abca4−/− Rhd8−/− mice without light exposure and 7 d after light exposure at 10,000 lx for 30 min was prepared by Epon-embedding. Arrows indicate cells in the subretinal space. Scale bars, 50 μm. INL, inner nuclear layer; IS, inner segment; ONH, optic nerve head; ONL, outer nuclear layer; OS, outer segment.

Flat-mount retinas from these mice 7 d after light exposure displayed many infiltrated cells into the subretinal space. These infiltrated cells stained positive for both Iba-1 (a marker for microglia/macrophage) and F4/80 (a marker for macrophage; Fig. 3B). Immunohistochemical analysis with anti–Iba-1, anti-NIMP-R14 (for neutrophil) and anti-CD3 (for T cell) Abs revealed that most of the subretinal cells were Iba-1–positive cells (Table II, Supplemental Fig. 3). A comparison of an SLO image and a flat-mount image with Iba-1 Ab staining is presented in Fig. 3C. The number of AF spots obtained using SLO and counting Iba-1+ cells in flat-mount retinas gave similar results. Retinal histology revealed loss of photoreceptor layers and nuclei of what appear to be infiltrating cells in the subretinal space in Abca4−/− Rhd8−/− mice 7 d after light exposure (Fig. 3D).

As a second approach, we generated Abca4−/− Rhd8−/− mice crossed with Cx3Cr1Igf2/a2 mice in which their monocytes express GFP (22). Flat-mount eyes after peeled off the neural retina were examined. Light-exposed Abca4−/− Rhd8−/− mice did not show

NIMP-R14 recognizes Ly6C in addition to Ly6G, and can therefore react with activated microglia/macrophages. As shown in Supplemental Fig. 3, subretinal cells with stronger signals over background or weakly stained cells were counted as positive cells.

Cryosections were prepared from every 200 μm distance from the edge to edge (eight slides per eye), and IHC was performed with anti–Iba-1 Ab for microglia/macrophage, anti–NIMP-R14 Ab for neutrophil and anti-CD3 Ab for T cell. Numbers of subretinal cells were counted from these sections, and the ratio of these cells was calculated.

Flat-mount eyes were prepared and subretinal cells with GFP, and autofluorescent signals were counted under fluorescent microscope.
GFP+ cells on the apical side of RPE layer, whereas Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice after induction of retinal light damage demonstrated GFP+ cells above the RPE layers (Fig. 4A). GFP+ cells were not detected before light exposure in either Cx3Cr1gfp/Abca4+/−/Rdh8−/− or in Abca4+/−/Rdh8−/− mice, indicating translocation of microglial/macrophage cells from the inner retina to the subretinal space. Ramified shaped GFP+ cells were observed only in the inner retina prior to light exposure, and no GFP+ cells were detected in the subretinal space (Fig. 4B, upper panel). In contrast, eyes of Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice 7 d after light exposure displayed increased numbers of more rounded GFP+ cells in the deeper retina close to the RPE layer (Fig. 4B, lower panel). Multiple GFP+ cells were observed in the outer nuclear layers (ONL) as well (Fig. 4C) and GFP+ cells were detected in the subretinal layers (Table II). SLO images of Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice with and without light exposure showed GFP signals from the inner plexiform layer where resting microglial cells normally reside (Fig. 4D, upper panel). Although there were no GFP signals from the level of the subretinal space (OS ~ RPE) before light exposure, GFP and AF signals were detected in the subretinal space of Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice following light exposure (Fig. 4D, lower panel). As the number of AF spots in light exposed Abca4+/−/Rdh8−/− mice is similar to that of GFP+ cells in Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice, it is likely that the AF spots detected with SLO are consistent with microglial cells. RPE flat-mount eyes 7 d after exposure to light at 10,000 lx for 30 min and flat-mount retina was prepared 7 d after light exposure (Fig. 5B). Absolute expression levels of Ccl3 gene, was increased in Ccl3−/−/Abca4+/−/Rdh8−/− mice compared with Abca4+/−/Rdh8−/− mice, thus indicating a loss of GFP+ cells in Ccl3−/−/Abca4+/−/Rdh8−/− mice after light exposure.

**FIGURE 4.** Translocation of macrophages during light induced retinal degeneration. (A) Flat-mount RPE was examined 7 d after light exposure at 10,000 lx for 30 min under a fluorescent microscope with 4-wk-old Cx3Cr1gfp/Abca4+/−/Rdh8−/− and Abca4+/−/Rdh8−/− mice. Scale bars, 25 μm. (B) Shapes of GFP+ cells were examined in 4-wk-old Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice by flat-mount eyes 7 d after exposure to light at 10,000 lx for 30 min at different depth of the retina. GFP signals are shown in green in the left and right panels and autofluorescent signals are shown in red. Scale bars, 25 μm. (C) GFP+ cells at the ONL ~ RPE level is presented. Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice were exposure to light at 10,000 lx for 30 min and flat-mount retina was prepared 7 d after light. Scale bar, 100 μm. (D) SLO images were captured from 4-wk-old Cx3Cr1gfp/Abca4+/−/Rdh8−/− mice before and 7 d after light exposure at 10,000 lx for 30 min. Scale bars, 100 μm. GCL, ganglion cell layer; IPL, inner plexiform layer; ONL, outer nuclear layer; RPE, retinal pigment epithelium.
compared with Abca4−/−Rdh8−/− mice. Expression of M1 and M2 macroglia/macrophage related molecules were also evaluated (Fig. 5D), because M1 macrophages contribute to inflammation, whereas M2 macrophages have an anti-inflammatory role (23). Nox2, a prototypic M1 microglia/macrophage marker (24) was increased in both Ccl3−/−Abca4−/−Rdh8−/− and Abca4−/−Rdh8−/− mice at 3 d after light exposure. However, expression of Arg1, a marker of M2 microglia/macrophage (17), was increased only in Abca4−/−Rdh8−/− mice 3 d after light. Tgfβ, an immunosuppressive factor and component of the immune-privilege in the eye (25), was elevated in Abca4−/−Rdh8−/− mice at 3 d, but returned to basal levels 7 d after light exposure.

Severe retinal degeneration develops in Ccl3−/−Abca4−/−Rdh8−/− mice after brief light exposure

Because Ccl3−/−Abca4−/−Rdh8−/− and Abca4−/−Rdh8−/− mice both exhibited similar levels of retinal degeneration after 30 min of light exposure at 10,000 lx, it is unclear what effect Ccl3 has on light-induced photoreceptor cell death. However, because Ccl3−/−Abca4−/−Rdh8−/− mice showed prolonged retinal inflammation after light exposure, we examined the effect of Ccl3 on mice exposed to 10,000 lx light for 15 min, which is only half the duration of our usual light exposure period. Ccl3−/−Abca4−/−Rdh8−/− mice exhibited severe retinal degeneration compared with Abca4−/−Rdh8−/− mice 7 d after light exposure (Fig. 6A). Furthermore, Ccl3−/−Abca4−/−Rdh8−/− mice exposed to 15 min of light showed higher Iba-1+ cell accumulation in the subretinal space and increased numbers of AF spots compared with Abca4−/−Rdh8−/− mice (Fig. 6B, 6C). Additional production of Ccl3 after light exposure at 10,000 lx for 15 min was observed in Abca4−/−Rdh8−/− mice, whereas Ccl3 production was not detected in Ccl3−/−Abca4−/−Rdh8−/− mice by ELISA (Fig. 6D). Furthermore, elevated production of Ccl4 was documented in Ccl3−/−Abca4−/−Rdh8−/− mice compared with Abca4−/−Rdh8−/− mice 1 and 3 d after light exposure. Increased production of Il1β (130.8 ± 53.5 pmol/eye in Ccl3−/−Abca4−/−Rdh8−/− mice versus 46.2 ± 8.8 pmol/eye in Abca4−/−Rdh8−/− mice) was also detected 1 d after light exposure in Ccl3−/−Abca4−/−Rdh8−/− mice. Taken together, these data indicate that Ccl3 deficiency exacerbates acute light-induced retinal degeneration with more production of Ccl4 in Abca4−/−Rdh8−/− mice.

Ccl3 deficiency moderates age-related retinal degeneration in Abca4−/−Rdh8−/− mice

Our previous studies showed that age-related retinal degeneration in Abca4−/−Rdh8−/− mice is characterized by chronic and sustained low-grade retinal inflammation (2, 16). To elucidate the role of CCL3 in chronic degeneration compared with light induced acute degeneration, the retinal phenotype of 6-mo-old Ccl3−/−Abca4−/−Rdh8−/− and Abca4−/−Rdh8−/− mice were examined. We found severe retinal degeneration in Abca4−/−Rdh8−/− mice compared with WT mice by SD-OCT, which displays a tangential...
view of the retina with ultrahigh resolution in vivo (26). Retinal degeneration in 6-mo-old Ccl3<sup>−/−</sup> Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> mice resembled WT mice (Fig. 7A, 7B), indicating reversal of the Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> phenotype in the absence of Ccl3. GFAP expression was also weaker in 6-mo-old Ccl3<sup>−/−</sup> Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> mice than in Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> mice (Fig. 7A, lower panel), indicating milder reactive gliosis against retinal inflammation. Furthermore, the number of AF spots, which represent subretinal microglial/macrophage cells (2), was also decreased in 6-mo-old Ccl3<sup>−/−</sup> Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> mice (Fig. 7C). Production of Ccl3 and Mertk were quantified with the eyes of 6-mo-old mice by ELISA (Fig. 7D). Production of Ccl3 and Ccl4 was quantified with the eyes of 6-mo-old mice by ELISA and Ccl4 was quantified by ELISA with eyes before and after light exposure. Error bars indicate SD of the means (n = 6). <sup>1</sup>*p < 0.05 versus light exposed Abca4<sup>−/−</sup> Rdh8<sup>−/−</sup> mice. Scale bars, 50 μm. (B) IHC by using anti-Iba-1, a marker of microglia/macrophage, 7 d after light exposure. Error bars indicate SD of the means (n > 6). <sup>2</sup>*p < 0.05. Ccl3 deficiency results in increased photoreceptor survival in a murine model of retinitis pigmentosa

The role of CCL3 in retinal degeneration was further examined in the Mertk<sup>−/−</sup> mouse model of retinitis pigmentosa. Mutations in the MERTK gene cause retinal dystrophies in humans and in animal models (27). MERTK belongs to a family of receptor tyrosine kinases that includes AXL and TYRO3, and it plays an indispensable role in the clearance of photoreceptor debris by RPE phagocytosis (28). Accumulation of photoreceptor debris in the subretinal space because of RPE phagocytosis deficiency is closely associated with the photoreceptor cell death seen in the Royal College of Surgeons rat with disabled Mertk and in Mertk<sup>−/−</sup> mice (29). To determine whether the retinal degenerative phenotype of Mertk<sup>−/−</sup> mice was altered in the absence of Ccl3, Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup> mice were generated, and the thickness of ONL in Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup> and WT mice was assessed at 5 and 8 wk of age by in vivo SD-OCT imaging. Mertk<sup>−/−</sup> mice showed degraded ONL compared with WT mice; however, Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup> mice had increased ONL thickness when compared with Mertk<sup>−/−</sup> mice, but was still less than WT mice (Fig. 8A). Representative retinal histology images of 5-wk-old Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup>, Mertk<sup>−/−</sup>, and WT mice are shown (Fig. 8B). Fewer numbers of Iba-1<sup>−/−</sup> cells were noted in Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup> mice than in Mertk<sup>−/−</sup> mice at 5 and 8 wk of age (Fig. 8C). Because inflammation in damaged retinas affects the integrity of the inner blood-retinal barrier (2), the integrity of this barrier in 8-wk-old Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup>, Mertk<sup>−/−</sup>, and WT mice was examined by fluorescent angiography. Whereas Ccl3<sup>−/−</sup> Mertk<sup>−/−</sup> mice showed only weak fluorescent dye leakage from the optic nerve head (ONH), Mertk<sup>−/−</sup> mice showed increased leakage not only from ONH but also from retinal
vessels (Fig. 8D). The incidence of fluorescent dye leakage in Ccl3−/−Mertk−/−, Mertk−/−, and WT mice from the ONH were 33.3%, 83.3%, and 0%, respectively. These findings indicate that the deficiency of Ccl3 contributed to milder retinal degeneration in the Mertk−/− mouse model of retinitis pigmentosa.

Ccl2 deficiency protects the retina from degeneration in mouse models

To elucidate the role of CCL3 and CCL2 further in the pathophysiology of retinal degeneration, Ccl2−/−Abca4−/−Rdh8−/− mice were generated by crossing Abca4−/−Rdh8−/− with Ccl2−/− mice. Ccl2−/−Mertk−/− mice were also generated. After light exposure at 10,000 lx for 30 min, Ccl2−/−Abca4−/−Rdh8−/− mice showed better preservation of the ONL (Fig. 9A, left panel) and fewer AF spots/Iba-1+ cells in the subretinal space (Fig. 9A, right panel) compared with Abca4−/−Rdh8−/− mice. Less severe age-related retinal degeneration with fewer AF spots was also observed in Ccl2−/−Abca4−/−Rdh8−/− mice compared with Abca4−/−Rdh8−/− mice at 6 mo of age (Fig. 9B). In addition, Ccl2−/−Mertk−/− mice revealed a more intact ONL when compared with Mertk−/− mice at 5 and 8 wk of age (Fig. 9C). Therefore, loss of Ccl2 resulted in milder retinal degeneration in all three models of retinal degeneration.

Discussion

Our previous studies with the retinal degeneration model of Abca4−/−Rdh8−/− mice implicated a role for RPE-derived chemokines and cytokines in recruitment of tissue microglia from the inner retina to the subretinal space (2). Although the increased number of Iba-1+ cells is likely due to infiltration, we cannot exclude the possibility that an increase in Iba-1+ cells is not due to cell proliferation. Retinal vascular endothelial cells are also a potential source of these chemokines in vivo, especially in recruitment of monocytes into the inner retina. In the current study, transcript level analysis of chemokines in the retina of Abca4−/−Rdh8−/− mice revealed selective elevation of Ccl3 and Ccl4 24 h after light exposure among tested chemokines. WT mice did not develop light-induced retinal degeneration and increased production of Ccl3 and Ccl4 was not documented. Furthermore, although most chemokines have overlapping targets in terms of receptor binding, by generating Ccl3−/−Abca4−/−Rdh8−/− mice, we demonstrated a nonredundant role for CCL3 in retinal degeneration.

CCL3 is likely produced by subretinally translocated tissue microglia from the inner retina where they normally reside, and this can be a trigger for additional monocyte infiltration from the circulation via inner retinal blood vessels. Prolonged activation of resident microglia is also observed in experimental herpes en-
Reproduction of the outer nuclear layer (ONL) is disrupted or abnormal (1). Our previous study implicated RPE cells as a source of chemokines that contribute to migration of cells to the subretinal space after light induced retinal damage (34). In addition to RPE cells, infiltrated microglia from the subretinal space also showed reactive gliosis in these cells (2). (32). Accumulating evidence in other chronic diseases implies that monocytes promote healing in cases of myocardial infarction (30–32). The ingestion of POS by RPE cells is essential for the maintenance of retinal health (33). However, RPE cells can also contribute to retinal inflammation when POS phagocytosis is disrupted or abnormal (1). Our previous study implicated RPE cells as a source of chemokines that contribute to migration of tissue microglia from the inner retina to the subretinal space (2). These microglial cells also ingest photoreceptor debris, and thereby display increased autofluorescence signals and increased production of proinflammatory and chemotactic cytokines. This results in further infiltration of monocytes from the circulation and promotes their migration from capillaries in the inner retina to the subretinal space. Previous studies using GFP-chimeras of myeloid cells had increased accumulation of monocytes in the subretinal space after light induced retinal damage (34). In addition to RPE cells and microglia, other cells produce Ccl3 including astrocytes and Müller cells. Of particular consideration is that light-exposed Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice showed reactive gliosis in these cells (2). Their interaction with the vascular endothelium might also be associated with chemokine production as observed in neural inflammation in the CNS (35, 36).

When Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> and littermate Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice were exposed to 10,000 lx of light for 30 min, light-exposed Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice showed delayed clearance of infiltrated microglia from the subretinal space compared with Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice. Although light-exposed Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>-Rdh8<sup>−/−</sup> mice did not secrete any Ccl3, a substantial increase of Ccl4 was observed in these mice compared with Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice after light exposure. Furthermore, Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice also displayed an increase of Ccl2 and Il1b, which are hallmarks of retinal inflammation after light (1). These observations indicate persistent retinal inflammation, which contributes to the severity of retinal degeneration in light-exposed Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice.

Results of the current study also show unchanged expression of Arg1, a marker of M2 macrophages in Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice before and after light exposure, whereas changes in expression of the Nos2 gene, which is a prototypic M1 marker (24), were observed in Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> and Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice. CCR2-associated M1 monocytes contribute to the digestion of damaged tissue, whereas Cx3Cr1-associated M2 monocytes promote healing in cases of myocardial infarction (30–32). Accumulating evidence in other chronic diseases implies that the lack of Arg1 elevation in light exposed Ccl3<sup>−/−</sup>Abca4<sup>−/−</sup>Rdh8<sup>−/−</sup> mice balances the local environment to inflammatory state and thus contributes to persistent retinal inflammation. We additionally showed data that supports a nonredundant role for CCL3 in a second model of retinal degeneration the Mertk<sup>−/−</sup> mouse. Ccl3<sup>−/−</sup>Mertk<sup>−/−</sup> mice displayed a less severe and less frequent impairment of the blood-retinal-barrier compared with Mertk<sup>−/−</sup> mice.
Macrophage/microglia has M1 and M2 subpopulations, which can regulate severity of AMD pathology (37, 38). M1 and M2 cells are also reported to play important roles in other inflammation models for many degenerative diseases (39). Persistent inflammation after traumatic brain injury is known to promote progression to Alzheimer disease (40). The proinflammatory M1 type microglia-based inflammatory mechanism has been shown to be involved in progression of posttraumatic brain injury to Alzheimer disease for over decades.

Studies of the Alzheimer disease model also implicated a role for CCL2-CCR2 interaction in activation of tissue microglial cells (39) and in the pathogenesis of age-related retinal degeneration in Ccl2−/− and Ccr2−/− mice (6, 41, 42). Conversely, CCL2 and CCR2 were found to have a harmful role in chronic oxidative stress-induced or inherited retinal degeneration, as Cc2 and Ccr2 gene knockout mice had less severe retinal degeneration (43, 44). In the current study, increased expression of Ccl2 in light-exposed Abca4−/− Rdh8−/− mice was observed, in addition to decreased retinal degeneration in Ccl2−/− Abca4+/− Rdh8−/− mice and in the Ccl2−/− Mertk−/− mouse were demonstrated. These data indicate that in our models, CCL2-CCR2 activation accelerates inflammation, possibly by recruiting M1 rather than M2 cells, and that preceded CCL3 production could affect CCL2-CCR2 interaction in degenerative conditions. Differential chemokine networks modulate the severity of disease phenotype, and improved understanding in each disease and disease state could largely contribute to future care of retinal diseases.

CCL3 and its receptors, CCR1 and CCR5, are therapeutic targets for treatment of HIV infection, multiple sclerosis, rheumatoid arthritis, diabetes, endometriosis, organ transplant rejection, and multiple myeloma (45). Given the current findings, CCL3, CCR1, and CCR5 are also potential targets for therapeutic intervention in retinal degeneration; however, further study is required to determine the role of this chemokine at each disease stage. Considering these results, a direct inhibition of microglial cells using drugs for antimicrobial activation, such as minocycline (46), might be beneficial to treat inflammation in degenerative retinal diseases.

In conclusion, this study revealed that production of chemokines was closely associated with degenerative retinal changes and microglia/macrophage translocation into the subretinal space. Regulatory mechanism of chemokine networks were differred in models of retinal degeneration. CCL3 showed a distinct role in pathogenesis of retinal degeneration under acute and chronic conditions in mouse models. Although a preceding increase in CCL3 from retinal microglial cells suggests the role of CCL3 as a potential master regulator of retinal inflammation, paradoxic effects of this chemokine in relationship to retinal degeneration could also explain the complex of pathology observed in retinal degeneration and other neurodegenerative diseases.

Supplemental Figure S1. CCL3 production from microglia
Primary retinal pigment epithelium (RPE) and retinal microglial cells were isolated from 2-week-old *Abca4<sup>-/-</sup>Rdh8<sup>-/-</sup>* mice. Co-incubation with 6 µg/100 µl purified mouse photoreceptor outer segments (POS) from *Abca4<sup>-/-</sup>Rdh8<sup>-/-</sup>* mice, 2 µM all-trans-retinal (atRAL), 1 µM lipopolysaccharide (LPS), 1 µM Pam3CSK4 (Pam) or PBS was performed for 24 h at 37 °C. Secreted protein amounts of Ccl3 and Ccl2 were measured by ELISA. Error bars indicate S.D. of the means (n > 3).* indicates P < 0.05 vs PBS treated microglia. # indicates P < 0.05 vs PBS treated RPE.
Supplemental Figure S2. SLO and SD-OCT images in Ccl3\(^{-/-}\) and Ccl2\(^{-/-}\) mice

Mice (6 wk old) were exposed to light at 10,000 lux for 30 min, and appearance of AF spot was examined 7 days after light exposure by SLO (upper). Retinal morphology was also evaluated by SD-OCT (lower). SLO (upper) and SD-OCT (lower) were also applied to 6 mo old mice. Bars in SLO and SD-OCT indicate 100 and 50 µm, respectively. No degenerative changes were observed.
Supplemental Figure S3. IHC for infiltrated cells into the subretinal space after light exposure in mice.

*Abca4−/−Rdh8−/−* mice at 4 weeks of age were exposed to light at 10,000 lux for 30 min, and cryosections were prepared 7 days after exposure. A. IHC was performed with anti-Iba-1 (for microglia/macrophage), anti-Nimp-R14 (for neutrophil) and anti-CD3 (for T cell) Abs. B. IHC with anti-Nimp-R14 and CD45 Abs are shown. Nimp-R14 staining display stronger (yellow arrow) and weaker (white arrows) signals. Bars indicate 30 µm. RPE, retinal pigment epithelial cell; ONL, outer nuclear layer; INL, inner nuclear layer.
Supplemental Figure S4. RPE damages in light exposed Ccl3−/−Abca4−/−Rdh8−/− and Abca4−/−Rdh8−/− mice

RPE flat mounts were made from Ccl3−/−Abca4−/−Rdh8−/− (TKO) and Abca4−/−Rdh8−/− (DKO) mice at 21 days after light exposure and from no light exposed Abca4−/−Rdh8−/− mice. Tight junction proteins between RPE cells were stained using anti-Zo-1 Ab (A). Size of RPE cell was measured in each mice group (B). Bars indicate 50 µm. Error bars indicate S.D. of the means (n > 5). * indicates P < 0.05.
