Human Airway Smooth Muscle Promotes Human Lung Mast Cell Survival, Proliferation, and Constitutive Activation: Cooperative Roles for CADM1, Stem Cell Factor, and IL-6

Fay Hollins,* Davinder Kaur,* Weidong Yang,* Glenn Cruse,* Ruth Saunders,* Amanda Sutcliffe,* Patrick Berger,2* Akihiko Ito,† Christopher E. Brightling,3* and Peter Bradding3,4*  

The microlocalization of mast cells within specific tissue compartments is thought to be critical for the pathophysiology of many diverse diseases. This is particularly evident in asthma where they localize to the airway smooth muscle (ASM) bundles. Mast cells are recruited to the ASM by numerous chemoattractants and adhere through CADM1, but the functional consequences of this are unknown. In this study, we show that human ASM maintains human lung mast cell (HLMC) survival in vitro and induces rapid HLMC proliferation. This required cell-cell contact and occurred through a cooperative interaction between membrane-bound stem cell factor (SCF) expressed on ASM, soluble IL-6, and CADM1 expressed on HLMC. There was a physical interaction in HLMC between CADM1 and the SCF receptor (CD117), suggesting that CADM1-dependent adhesion facilitates the interaction of membrane-bound SCF with its receptor. HLMC-ASM coculture also enhanced constitutive HLMC degranulation, revealing a novel smooth muscle-driven allergen-independent mechanism of chronic mast cell activation. Targeting these interactions in asthma might offer a new strategy for the treatment of this common disease. The Journal of Immunology, 2008, 181: 2772–2780.

vitro are sparse. However, human lung mast cells (HLMC) adhere to human ASM cells, in part, via an Ig superfamily member known as CADM1 (19) (previously known as TSLC1, IGSF4, SgIGSF, SynCAM, NecI2, RA175), suggesting that specific cellular cross-talk occurs. In addition, potential mechanisms of mast cell recruitment by the ASM have been identified, particularly the CXCR3/CXCL10 axis (20).

In addition to mast cell recruitment and adhesion, it is likely that the HLMC hyperplasia present within asthmatic ASM depends upon the ability of the ASM to maintain HLMC survival and could also result in part from the proliferation of resident HLMC. It is well established that primary differentiated HLMC have the potential to proliferate (21, 22) and ASM is known to produce the mast cell growth and survival factors stem cell factor (SCF) and IL-6 (23, 24). In this study, we show for the first time that ASM not only maintains HLMC survival in vitro, but a direct interaction between the two cell types leads to the rapid proliferation of HLMC through a cooperative SCF-, IL-6-, and CADM1-dependent mechanism. This is coupled with enhanced constitutive HLMC activation. Targeting this interaction in the ASM compartment in asthma might offer a new strategy for the treatment of this increasingly common disease.

**Materials and Methods**

**Reagents and cytokines**

Antibiotic/antimycotic solution, CFSE (Cell Trace CFSE Cell Proliferation Kit), DMEM, HEPES, HBSS without Ca\(^{2+}\) and Mg\(^{2+}\), and nonessential amino acid solution were all purchased from Invitrogen Life Technologies. The 4′,6-diamido-2-phenylindole (DAPI), heat-inactivated FCS, ITS plus 3 liquid medium supplement and sodium pyruvate were obtained from Sigma-Aldrich.

Recombinant human IL-6, IL-10, and SCF were obtained from R&D Systems. Accutase enzyme cell detachment medium was purchased from Biochrom. Transwell 0.4 µm inserts were purchased from Becton Dickinson Labware. Histamine and S-adenosyl-l-methyl-\(^{3}H\)methionine were purchased from Amershams Life Science; rat kidney histamine methyl transferase was a generous gift from Dr. S. Harper (Astra Charnwood, Loughborough, U.K.). RIPA buffer containing protease inhibitors and protein A/G beads were purchased from Santa Cruz Biotechnology.

**Antibodies**

The following Abs were purchased from R&D Systems: anti-human IL-6 mAb (clone 6708), chicken IgY isotype control, goat anti-human SCF, IgG1 isotype control and secondary NorthernLights, PE (RPE). Anti-human CD117-RPE mAb (clone 104D2) and isotype IgG2a-FITC were obtained from DAKO. Anti-human myosin mAb (clone, SMMS-1), anti-human α-smooth muscle actin-FITC mAb (clone, 1A4), and goat IgG control were purchased from Sigma-Aldrich. Anti-human CD117 (clone, YB5B8), Annexin V, IgG1-RPE, and propidium iodide (PI) were purchased from BD Pharmingen. Human myeloma IgE was obtained from Calbiochem-Novabiochem. Allophycocyanin goat anti-mouse secondary and antimouse IgG-FITC direct conjugate and myosin indirect conjugate, goat anti-human SCF [goat IgG] and IL-6 [mouse IgG1] and for anti-CADM1 [chicken IgY]) were included when required alone or in combination with 0.4 µM Transwell inserts to prevent cell contact between the two cell types. Because analysis of bronchial biopsies reveals a mean mast cell density in asthmatic ASM bundles of ~4 ASM cell:1 HLMC, HLMC were seeded onto confluent FCS-starved ASM at a 1:4 ratio (equivalent to 4–10 HLMC well). Cell number during the culture period was assessed using Kimura staining, which readily differentiates red metachromatic mast cells from unlabeled ASM cells. HLMC monoculture controls were established in parallel and included mast cells in FCS-free and cytokine-free media, mast cells with the cytokines SCF (100 ng/ml) and IL-6 (50 ng/ml) but no FCS, and mast cells with SCF, IL-6, and 10% FCS.

**Quantification of HLMC death by flow cytometry**

HLMCs taken from culture 3 days following isolation were washed with FCS-free media and seeded onto confluent ASM that had been FCS-deprived for 3 days in 6-well plates in DMEM media containing 1% ITS plus 3 liquid media supplement, 1% anti-biotic/anti-mycotic, 1% nonessential amino acids, and 1% sodium pyruvate. Abs (anti-human SCF [1 µg/ml]; anti-human IL-6 [0.6 µg/ml]; anti-CADM1 9D2 [10 µg/ml], isotype controls for anti-human SCF [goat IgG] and IL-6 [mouse IgG1] and for anti-CADM1 [chicken IgY]) were included when required alone or in combination with 0.4 µM Transwell inserts to prevent cell contact between the two cell types. Because analysis of bronchial biopsies reveals a mean mast cell density in asthmatic ASM bundles of ~4 ASM cell:1 HLMC, HLMC were seeded onto confluent FCS-starved ASM at a 1:4 ratio (equivalent to 4–10 HLMC well). Cell number during the culture period was assessed using Kimura staining, which readily differentiates red metachromatic mast cells from unlabeled ASM cells. HLMC monoculture controls were established in parallel and included mast cells in FCS-free and cytokine-free media, mast cells with the cytokines SCF (100 ng/ml) and IL-6 (50 ng/ml) but no FCS, and mast cells with SCF, IL-6, and 10% FCS.

**Dye quantification of HLMC cell proliferation**

HLMC were seeded at a density of 0.5 × 10^6 cells per 24-well plate in medium containing 10% FCS and 1% ITS. ASM were grown at a ratio of 4 ASM cell:1 HLMC. HLMC were seeded at a density of 0.5 × 10^6 cells per T75 flask in either FCS free and cytokine free ITS media or in the presence of 10% FCS and exogenous cytokine (IL-6 and SCF) media. ASM had been grown to confluence in T75 flasks and FCS deprived for 3 days in ITS media before coculturing with HLMC (at a ratio of 1:4 HLMC:ASM). The HLMC were then incubated at 37°C for 6 days either in the presence or absence of ASM cells in ITS or just in the presence of FCS and cytokines. After days 1, 3, 7, and 10, the cell supernatant from the cultures were spun down and kept and the cells were washed with HBSS, harvested with Accutase and pooled with their respective supernatant pellets and washed that may have detached the cells during the experiment. In brief, for HLMC alone the percentage of apoptotic or necrotic cells was assessed by suspending the HLMC cells in 1× Annexin binding buffer containing FITC-conjugated Annexin V (1 µg/200 µl binding buffer) ± PI (0.5 µg/ml), before analysis on the BD FACS Canto flow cytometer. Three-color flow cytometry was conducted with HLMC cocultured with ASM cells. The cocultured cultures were stained with mAb against CD117 (clone, YB5B8) and then with allophtococyanin secondary (to identify the HLMC) and then stained as above with Annexin and PI. Appropriate isotype controls were used.

**Morphological detection of HLMC apoptosis**

Nuclear morphology of HLMC was assessed by DAPI staining. For these experiments, HLMC were seeded at a density of 1 × 10^6 cells/well into 8-well chamber slides in either FCS-free and cytokine-free ITS media or in the presence of 10% FCS and exogenous cytokine IL-6-50 ng/ml SCF 100 ng/ml media. ASM cells had been grown to confluence in 8-well chamber slides and FCS deprived for 3 days in ITS media before coculturing with HLMC (at a ratio of 1:4 HLMC:ASM). The HLMC were then incubated at 37°C for 6 days either in the presence or absence of ASM cells in ITS or just in the presence of FCS and cytokines. ASM cells cocultured...
ASM SUPPORTS MAST CELL PROLIFERATION

FIGURE 1. HLMC survive and proliferate in coculture with ASM in the absence of FCS and exogenous cytokines. A, Numbers of metachromatic mast cells present over 10 days of culture in culture medium alone (black line), SCF (100 ng/ml) and IL-6 (50 ng/ml) (blue line), medium plus SCF/IL-6/FCS (green line), and coculture with ASM in the absence of SCF/IL-6/FCS (red line); n = 14 experiments using 8 HLMC donors and 14 ASM donors. **, p < 0.01; and ***, p < 0.001 by ANOVA. †, p < 0.05 by Tukey’s multiple comparison test comparing HLMC-ASM coculture to each of the other conditions. B, HLMC were loaded with CFSE before culturing in SCF/IL-6/FCS (green line) or coculture with ASM in the absence of SCF/IL-6/FCS (red line) for 10 days, and then analyzed using flow cytometry. Cocultured HLMC exhibit a subpopulation with significantly reduced fluorescence beyond the control HLMC population, indicating the presence of a proliferating pool of cells (p = 0.046 by paired t test). The histogram is representative of three experiments using three HLMC donors and three ASM donors. C, Analysis of CFSE staining using Modfit LT software revealed the presence of a reduced number of generations following 10 days in monocyte (i) compared with ASM-coculture (ii). Representative of three experiments. D–F, The percentage of dead/apoptotic cells over 10 days of culture. D, Representative dot plots for FITC-Annexin V/PI dual-color flow cytometry of HLMC cultured for 7 days (i) alone in the absence of SCF/IL-6/FCS and (ii) alone with SCF/IL-6/FCS. Three color flow cytometry of 7-day HLMC labeled with CD117-allophycocyanin cocultured with ASM in the absence SCF/IL-6/FCS (iii), and gated CD117 cells analyzed for Annexin V and PI (iv). E, Percentage of dead cells revealed by PI staining using flow cytometry. F, Percentage of apoptotic cells revealed by Annexin V staining using flow cytometry. G, Representative micrographs at day 7 showing DAPI staining (i) in absence of SCF/IL-6/FCS, (ii) in coculture with ASM (stained with DAPI and overlaid with anti-CD117 [red]). In i and ii, note nuclear blebbing (arrows) and fragmentation (arrowheads). H, Quantification of apoptosis identified by nuclear morphology. Fig. 1E, F, and H: *, p < 0.05; **, p < 0.01; and ***, p < 0.001 comparing HLMC monocyte in the presence or absence of SCF/IL-6/FCS to HLMC-ASM coculture. Paired t test; n = 3 HLMC and ASM donors.

with HLMC were stained with directly conjugated mAb against RPE-CD117 (clone 104D2) and indirectly labeled with secondary Northen-Lights RPE secondary. The cells were then counterstained with DAPI and mounted with photo bleed retardant mounting medium. CD117 was used to identify the HLMC in the presence of ASM cells. HLMC cultured alone were harvested and cytopsin down onto slides and stained with DAPI alone and mounted. For each HLMC mono- or coculture (n = 3), six random high-powered fields were examined for morphologic features of apoptosis such as nuclear condensation and fragmentation.

Immunofluorescence and confocal microscopy

ASM were grown to confluence on chamber slides and FCS deprived for 3 days and then 5 × 10⁴ HLMC were added to the cells for 3 days. The cells were fixed with methanol, blocked with 3% BSA, and labeled with conjugated mAb against RPE-CD117 (clone 104D2) and indirectly labeled with secondary Northen-Lights RPE secondary. The cells were also labeled with chicken anti-human CADM1 IgY mAb (3E1) indirectly labeled with FITC-labeled goat anti-IgY polyclonal. Cells were counterstained with DAPI and mounted with photo bleach-retardant mounting medium. Appropriate isotype controls were performed. The cells were either studied by a standard fluorescent microscope or visualized using an Olympus Optical FV500 scanning laser confocal IX70 inverted microscope. Images were captured using an oil immersion ×60 objective. Digital images and data files of immunofluorescence intensity transectioning specimens in the xy plane and x,y,z plane were recorded using Flowview software (FV300 Olympus). Images were rendered using paintshop pro 8.

SCF expression

Flow cytometry. Confluent ASM cells in T25 flasks were FCS deprived for 24 h, washed with HBSS, and harvested using Accutase. ASM were stained with goat anti-human SCF, indirectly labeled with polyclonal rabbit anti-goat FITC secondary, and compared with appropriate goat isotype control. Analysis was performed using single-color flow cytometry on the BD FACSCanto flow cytometer.

Immunofluorescence. ASM were grown to confluence on chamber slides and FCS deprived for 24 h. The cells were labeled with goat anti-human SCF, indirectly labeled with polyclonal rabbit anti-goat FITC secondary, and compared with appropriate goat isotype control. Cells were counterstained with DAPI and mounted.
Mast cell activation for histamine release

HLMC were activated using IgE and anti-IgE stimulation. HLMC were harvested and sensitized with human myeloma IgE (2.4 μg/ml) for 1 h before washing and resuspending at 37°C in fresh medium containing goat anti-human IgE (1/1000 dilution). After 30-min incubation, supernatant was collected and the cell pellet was lysed in sterile de-ionized water. Histamine was measured by sensitive radioenzymatic assay based on the conversion of histamine to methylhistamine in the presence of the enzyme histamine-N-methyltransferase as previously described (26).

Immunoprecipitation of CADM1 and Western blotting

A total of 8 × 10⁷ HMC-1 cells were lysed in 4 ml ice-cold RIPA buffer containing protease inhibitors. The insoluble debris was removed by centrifugation at 10,000 g for 10 min. The cell lysate (4 ml) was then incubated with 80 μl protein A/G beads (Santa Cruz Biotechnology) overnight at 4°C with rotation to remove any proteins that adhere nonspecifically. The beads were pelleted by centrifugation and the 4 ml “cleaned” cell lysate was incubated with 20 μl goat anti-chicken IgY (final concentration 10 μg/ml). These samples were incubated for 4 h at 4°C. Protein A/G beads were then added to all samples (20 μl beads/ml sample) and incubated at 4°C overnight with rotation. The samples were then centrifuged, and the supernatant diluted at 1/100 in sample loading buffer. The beads were washed four times with PBS, and beads in each sample then resuspended in 200 μl sample loading buffer. All samples were boiled for 10 min and stored at −20°C before running on a 10% SDS gel. After transfer to polyvinylidene difluoride membrane, the membrane was probed for CADM1 using mouse IgG1 anti-CD117 Ab (0.2 μg/ml) and visualized by goat anti-mouse IgG-HRP.

Statistical analysis

Statistical analysis was performed using GraphPad Prism 4 (GraphPad). Data are presented as mean ± SEM. Paired and unpaired experiments were analyzed by using paired and unpaired t tests, respectively. Comparison across groups was assessed using ANOVA and Tukey’s multiple comparison test where appropriate. Differences were considered significant when p values were less than 0.05.

Results

ASMC supports the survival and proliferation of HLMC

When HLMC (4 × 10⁴) were incubated in culture medium alone, their numbers diminished to zero by day 10 (Fig. 1A). In the presence of IL-6 and SCF, but no FCS, 1.5 ± 0.35 × 10⁴ HLMC survived by day 10 (Fig. 1A), while SCF/IL-6 plus 10% FCS sustained survival with minor proliferation evident by day 10 (5.2 ± 0.67 × 10⁴; Fig. 1A). Remarkably, when HLMC were cocultured with asthmatic or nonasthmatic ASMC (4:1 ASMC:HLMC ratio) in the absence of FCS or exogenous cytokines, not only did they survive, but there was rapid proliferation evident from day 1 and, at day 10, the number of mast cells had increased to 12.2 ± 1.0 × 10⁴ (n = 14, p < 0.001; Fig. 1A). The HLMC number from days 1–10 in ASMC coculture was significantly greater than each of the other conditions (Fig. 1A). This survival and proliferative effect of the ASMC did not differ between asthmatic or nonasthmatic ASMC cells (p = 0.34).

To confirm the results obtained by cell counting, the proliferation of HLMC in ASMC coculture was quantified using HLMC that were preloaded with the fluorescent marker CFSE. This stable dye is not passed between cells upon adhesion and is split equally upon cell mitosis, allowing detection of new generations using flow cytometry. Loaded HLMC were cocultured with ASMC for 10 days or cultured alone in SCF/IL-6/FCS-supplemented medium (positive control). The proportion of HLMC that proliferated in coculture was significantly greater than the control (mean difference [95% confidence interval] 16.4% [0.7–32.2%]; p = 0.046; n = 3; Fig. 1B). The fluorescence histograms were also analyzed using ModFit LT software, which accurately approximates generation peaks. Cocultured HLMC were found to contain more generations following 10 days of culture when compared with the control HLMC (Fig. 1C).

HLMC apoptosis is attenuated in ASMC coculture

The extent of cell death in the various culture conditions was analyzed using a combination of PI and Annexin V staining, with DAPI staining of the nuclei. PI and Annexin V analysis of cell death was assessed using flow cytometry in combination with CD117-allophycocyanin to identify the HLMC population (Fig. 1D). Staining with PI demonstrated that HLMC cell death in both the ASMC coculture and the SCF/IL-6/FCS-supplemented monoculture was relatively low and stable (Fig. 1E). In contrast, HLMC in the cytokine-free monoculture demonstrated accelerated cell death (Fig. 1E).
Annexin V staining on HLMC increased consistently in the SCF/IL-6/FCS-supplemented control compared with the ASM coculture suggesting a decreased rate of apoptosis in coculture (p < 0.001 at day 7; Fig. 1F). This was further supported by analysis of nuclear fragmentation using DAPI staining (Fig. 1, G and H). By day 3, there was a significant increase in the percentage of apoptotic HLMC nuclei in the SCF/IL-6/FCS-supplemented control compared with the HLMC in ASM coculture (p = 0.011). There was some discrepancy in the number of apoptotic HLMC nuclei analyzed by Annexin V vs DAPI in the SCF/IL-6/FCS-supplemented mononucleotide. This may be accounted for by the degranulation of HLMC following resuspension in 100 ng/ml SCF (27). Nevertheless, the data demonstrate consistently greater cell death within the SCF/IL-6/FCS-supplemented HLMC mononucleotide compared with the HLMC in ASM coculture.

**ASM-induced HLMC proliferation is dependent on SCF-, IL-6-, and CADM1-dependent adhesion**

SCF is an essential mast cell growth factor (28–30), IL-6 promotes cord blood mast cell progenitor growth (31) and prevents HLMC apoptosis (32), and both cytokines are produced by ASM (23, 24). IL-6 concentrations in the HLMC-ASM coculture-conditioned medium at day 3 were 12.2 ± 0.67 ng/ml, which is above the optimal 1 ng/ml concentration of IL-6 required for the development of human mast cells from peripheral blood progenitors (30). SCF concentrations in this medium were only 0.29 ± 0.06 ng/ml, which exerts only a weak survival capacity on cultured human mast cells (30). However, SCF also exists in a membrane-bound form generated by alternative mRNA splicing (33). Membrane-bound SCF was highly expressed as demonstrated by both flow cytometry and immunofluorescent staining in ASM from both asthmatics and nonasthmatic patients (Fig. 2A). Addition of neutralizing Abs targeting SCF or IL-6 inhibited HLMC proliferation in ASM coculture to a similar degree, and using both Abs together had no significant additive effect (Fig. 2B). With cytokine neutralization, cell number at day 10 remained similar to that present at day 0, suggesting that while both IL-6 and SCF play important roles in mediating HLMC proliferation, a further factor was supporting their survival.

**FIGURE 3.** HLMC proliferation in coculture with ASM is dependent on cell-cell contact and CADM1. A, In the presence of ASM-conditioned media, HLMC survived for 7 days but did not proliferate (red line). This survival effect was attenuated equally by neutralizing Abs to IL-6 (blue line) and SCF (green line), with a nonsignificant additive effect evident with both SCF and IL-6 neutralization (purple line), n = 6 experiments using three HLMC donors and six ASM donors. **, p < 0.01; and ***, p < 0.001 by one-way ANOVA. †, p < 0.05 by Tukey’s multiple comparison test comparing HLMC cultured in ASM-conditioned to addition of combined SCF and IL-6 neutralizing Abs. B, Separation of HLMC from ASM cells using a 0.4 μm Transwell insert inhibits their proliferation and survival. HLMC were cultured in media alone (black solid line), exogenous SCF/IL-6/FCS (light green solid line solid line), or in the presence of ASM without SCF/IL-6/FCS (red solid line). HLMC were also cocultured with ASM with separation by a 0.4 μm Transwell insert (T) to block physical contact between the two cell types in the presence and absence of isotype control Ab (red and gray dashed line respectively), neutralizing anti-IL-6 Ab (blue dashed line), neutralizing anti-SCF Ab (green dashed line), or both anti-IL-6 and -SCF (purple dashed line), n = 5 experiments using three HLMC donors and six ASM donors. **, p < 0.01 by one-way ANOVA. †, p < 0.05 by Tukey’s multiple comparison test comparing cocultured HLMC to the addition of Transwell inserts in the presence and absence of neutralizing Abs. C, In keeping with the Transwell experiments, addition of an adhesion-blocking Ab to CADM1 also prevented HLMC proliferation in coculture with ASM, suggesting that CADM1-dependent adhesion is an important component of the AS-induced HLMC proliferation pathway, n = 5 experiments using three HLMC donors and five ASM donors. **, p < 0.01 by paired t test comparing isotype control cocultured HLMC with the anti-CADM1 Ab. D, HLMC-ASM coculture in the presence of neutralizing Abs to SCF, IL-6, and CADM1 revealed a minor additional effect over neutralization of each in isolation suggesting a cooperative effect between the three molecules, n = 6 experiments using three HLMC donors and six ASM donors. *, p < 0.05; **, p < 0.01; and ***, p < 0.001 by paired t test comparing isotype control cocultured HLMC with anti-SCF/IL-6/CADM1-treated cells.
To address whether ASM-induced HLMC survival and proliferation requires cell-cell contact or soluble factors only, HLMC were cultured in FCS-free ASM-conditioned medium generated over 3 days. The soluble mediators within the media maintained HLMC survival for 7 days but no proliferation was evident (Fig. 3). By day 10, HLMC numbers began to decline, indicating a possible depletion of survival factors. Addition of SCF- or IL-6-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further (Fig. 3A).

We then examined ASM-dependent HLMC survival and proliferation using the Transwell system. ASM cells were grown to confluence before a 0.4 μm Transwell membrane was inserted and the HLMC then added (4:1 ASM:HLMC ratio as previously). Use of the Transwell inserts significantly reduced survival and proliferation of the HLMC compared with the coculture without inserts (Fig. 3B), comparable to the effects seen in ASM-conditioned media. Addition of IL-6- or SCF-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further (Fig. 3A).

We then examined ASM-dependent HLMC survival and proliferation using the Transwell system. ASM cells were grown to confluence before a 0.4 μm Transwell membrane was inserted and the HLMC then added (4:1 ASM:HLMC ratio as previously). Use of the Transwell inserts significantly reduced survival and proliferation of the HLMC compared with the coculture without inserts (Fig. 3B), comparable to the effects seen in ASM-conditioned media. Addition of IL-6- or SCF-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further, indicating a possible depletion of survival factors. Addition of SCF- or IL-6-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further (Fig. 3A).

We then examined ASM-dependent HLMC survival and proliferation using the Transwell system. ASM cells were grown to confluence before a 0.4 μm Transwell membrane was inserted and the HLMC then added (4:1 ASM:HLMC ratio as previously). Use of the Transwell inserts significantly reduced survival and proliferation of the HLMC compared with the coculture without inserts (Fig. 3B), comparable to the effects seen in ASM-conditioned media. Addition of IL-6- or SCF-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further, indicating a possible depletion of survival factors. Addition of SCF- or IL-6-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further (Fig. 3A).

We then examined ASM-dependent HLMC survival and proliferation using the Transwell system. ASM cells were grown to confluence before a 0.4 μm Transwell membrane was inserted and the HLMC then added (4:1 ASM:HLMC ratio as previously). Use of the Transwell inserts significantly reduced survival and proliferation of the HLMC compared with the coculture without inserts (Fig. 3B), comparable to the effects seen in ASM-conditioned media. Addition of IL-6- or SCF-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further, indicating a possible depletion of survival factors. Addition of SCF- or IL-6-neutralizing Abs or both in combination to this culture reduced the number of surviving HLMC further (Fig. 3A).

HLMC adhere to ASM in part through CADM1, an adhesion molecule highly expressed on HLMC but not ASM (19). Interestingly, the adhesion-blocking anti-CADM1 mAb 9D2 (19) significantly reduced the proliferation of HLMC in ASM coculture compared with the isotype control (p < 0.01 at days 7 and 10; Fig. 3C), indicating that adhesion via CADM1 is also a critical factor for the induction of HLMC proliferation by ASM. Inhibiting CADM1, IL-6, and SCF together (Fig. 3D) reduced the survival and proliferation of HLMC further than that seen with the individual Abs (p = 0.007 at day 10 by one-way ANOVA). Nevertheless, this inhibition was not complete and 56.9 ± 25.5% of HLMC remained viable in the culture after 10 days, indicating that either blockade of these molecules was not complete or a further factor(s) may be important. There was no evidence of any physical or functional cross-reaction between the anti-SCF, anti-IL-6, or 9D2 anti-CADM1 Abs. Taken together, the marked effects of inhibiting each of SCF, IL-6, and CADM1 in isolation, but relatively small additive effects seen when inhibiting them together, suggests the presence of a cooperative interaction between these three molecules.

**CD117 and CADM1 colocalize and physically interact in HLMC**

Our data suggest that there is a cooperative interaction between SCF and CADM1. It is possible, therefore, that CADM1-dependent adhesion facilitates the interaction of membrane-bound SCF on human ASM with its receptor CD117 (c-kit) on HLMC. Confocal immunofluorescence demonstrated strong colocalization of CD117 and CADM1 in the HLMC plasma membrane (Fig. 4A–D). There was evidence of immunofluorescent hotspots for both CADM1 and CD117, which were 100% colocalized and present at points of adhesion with ASM (Fig. 4). Interestingly, immunoprecipitation of CADM1 resulted in the formation of a 120 kDa complex that included CD117, suggesting that CADM1 and CD117 interact in vivo. This interaction may be important for the survival and proliferation of HLMC and warrants further investigation.
HLMCs in coculture with ASM demonstrated increased constitutive histamine release and decreased histamine content. The level of histamine release was measured in the culture supernatant and corrected for the number of cells present at the appropriate time point. Increased constitutive histamine release was evident in the HLMC-ASM coculture at both days 5 and 10 compared with the SCF/IL-6/FCS-supplemented monoculture control. The increased HLMC number in the coculture compared with both the monoculture control and the original cells at baseline was similar to that at day 0 (Fig. 5A). Although the 10-day cocultured HLMC contained less histamine than the day 0 controls, when they were activated with IgE/anti-IgE for 30 min, the total amount of histamine released was similar to that at day 0 (Fig. 5C). Thus, HLMC are constitutively activated while in coculture with ASM, and maintain their responsiveness to stimulation through the high-affinity IgE receptor.

**Discussion**

We show for the first time that human ASM supports the survival and proliferation of HLMC, effects mediated through a cooperative interaction between ASM membrane-bound SCF, HLMC membrane-expressed CADM1, and soluble IL-6. Furthermore, HLMC in ASM coculture demonstrate enhanced constitutive activation as measured by the release of histamine.

Human ASM was predicted to maintain HLMC survival because it produces SCF, an essential mast cell growth factor (23). However, the rapid proliferation of HLMC was remarkable, particularly as they have long been considered to represent terminally differentiated cells. Nevertheless, HLMC will survive and proliferate slowly over many weeks in culture with SCF, IL-6, and IL-10 (21, 22), but this is in marked contrast to the rapid rate of HLMC proliferation in the ASM coculture. High-resolution dye tracking confirmed the results observed by metachromatic counting, while DAPI and Annexin V staining indicated a decreased rate of HLMC apoptosis in the ASM coculture compared with the HLMC SCF/IL-6/FCS-supplemented monoculture. The increased HLMC numbers evident in ASM coculture compared with the cytokine monoculture is, therefore, due to both proliferation and protection from apoptosis.

Cell-cell contact was an essential requirement for HLMC proliferation in coculture with HLMC. The effect of cell separation by a Transwell membrane was largely mimicked by an adhesion-blocking Ab to CADM1, a Cα2+ independent adhesion molecule known to mediate, in part, the adhesion of HLMC to ASM (19), and the adhesion of mouse mast cells to fibroblasts (34) and nerves (25). Homophilic CADM1 interactions in epithelial cells promote its tumor suppressor activity, but its heterophilic ligation in HLMC clearly promotes cell proliferation. A potential mechanism that would explain this is a specific interaction with the SCF receptor CD117 (c-kit). Several lines of evidence support this hypothesis. Firstly, the effects of blocking CD117 and CADM1 were only marginally additive, suggesting a cooperative interaction. The SCF expressed by ASM was predominantly membrane-bound, and we also observed strong colocalization of CD117 and CADM1 in the HLMC plasma membrane. Furthermore, and perhaps most importantly, CD117 coimmunoprecipitated with CADM1, indicating a physical interaction. Interestingly in mouse mast cells, CD117-dependent signaling through PI3K has been shown to be important for CADM1-dependent adhesion (35), although this does not appear to apply to humans (19). Finally, there is a precedent for the interaction of CADM1-like molecules with other tyrosine kinase receptors. For example, CADM1 binds a membrane guanylate kinase family member, Pals2, which binds to Lin-7. Lin-7 is required for the correct membrane localization of an epidermal growth factor receptor homologue in Caenorhabditis elegans (36). Thus, the ability of CADM1 to mediate HLMC adhesion to ASM, its direct
physical interaction with CD117, and its apparent cooperative role in CD117-dependent signaling suggests that CADM1 plays a fundamental role in many CD117-dependent mast cell processes. We, therefore, envisage a model whereby CADM1-dependent adhesion and CADM1-dependent CD117 membrane localization facilitates the interaction of CD117 with membrane-bound SCF on ASM and other stromal cells.

IL-6 was also an important mediator of the HLMC proliferative response in the coculture environment. The concentrations present in the coculture supernatant were above the optimal concentration required to promote cultured human mast cell proliferation (30). The source of this IL-6 might be ASM but could also arise from HLMC, which release this cytokine in large quantities (32, 37). IL-6 appeared to cooperate with SCF and CADM1 as its contribution was similar to these molecules and the effects of its blockade were barely additive. Determining how IL-6 interacts with SCF and CADM1 requires further investigation.

Human gut fibroblasts maintain gut mast cell survival but do not induce their proliferation. This did not require cell-cell contact and was not mediated via SCF (38), which is surprising as SCF- and CADM1-dependent adhesion mediates mouse mast cell adhesion to fibroblasts and promotes their survival (34, 35). The gut fibroblast survival activity had a mass between 10 and 100 kDa, suggesting that IL-6, which was not measured, may have been partially responsible. In contrast, coculture of human gut mast cells with HUVECs not only promoted mast cell survival but also induced their proliferation (39). However the proliferative effect was much slower than that seen in our experiments with ASM and the mechanism was distinct. Although gut mast cell-HUVEC coculture required adhesion for proliferation, the adhesive process was mediated via membrane-bound SCF and the Ig superfamily molecule VCAM-1 expressed on HUVEC (39). Neither of these is involved in the adhesion of HLMC to ASM (19). Furthermore, blocking SCF in coculture with HUVECs killed all mast cells, whereas in our experiments, proliferation was attenuated but the cells remained viable. Human bronchial epithelial cells also maintain the survival of human cord blood-derived mast cells through a SCF-dependent mechanism but over 4 days do not induce proliferation (40). Determining whether HLMC interact with airway epithelial cells, endothelial cells, and fibroblasts via CADM1 will be of great interest.

Not only do HLMC proliferate in coculture with ASM, but they are also activated. There was increased basal histamine release during the coculture period, which was mirrored by a decrease in HLMC histamine content. This is particularly interesting because mast cells in the asthmatic ASM bundle are activated as shown by the presence of piecemeal degranulation (14). Our data, therefore, suggests that this can occur as a result of the interaction of mast cells with ASM independently of allergen and/or monomeric IgE (4). This might explain why anti-IgE therapy is able to inhibit airway inflammation but have no effect on AHR (41). The mechanisms behind this require investigation but could be mediated in part through the interaction of HLMC CD117 with membrane-bound SCF expressed by ASM. It will also be important to investigate the role of CADM1 in this activation process. Of further importance, these activated, histamine-depleted HLMC are still able to release equivalent amounts of histamine following IgE-dependent activation, indicating that they can still respond to allergen inhalation. These findings are in contrast to those with human airway epithelium, which actually inhibits constitutive and IgE-dependent mast cell activation (40, 42), further highlighting the potential importance of the ASM-HLMC interaction.

In summary, we have demonstrated that human ASM supports HLMC survival and proliferation which may contribute to the mast cell myelitis evident in asthma. Furthermore, this interaction activates mast cells, which supports the view that they aggravate smooth muscle contractile dysfunction in asthma. Perturbing the SCF-CADM1-IL-6-dependent pathway through which these effects are achieved may offer a new approach to asthma therapy.
