NF- κ B p50 Regulates C/EBP α Expression and Inflammatory Cytokine-Induced Neutrophil Production¹

Dehua Wang,² Ido Paz-Priel,² and Alan D. Friedman³

NF- κ B is a key transcriptional inducer of the inflammatory response in mature myeloid cells, and also stimulates cell survival, but its role in immature myeloid cell development has not been well characterized. C/EBP α is required for the development of monocytic and granulocytic myeloid cells from early progenitors, and NF- κ B and C/EBP β cooperatively induce several inflammatory mediators. Having found that C/EBP α binds NF- κ B p50 preferentially compared with NF- κ B p65, we have now investigated myelopoiesis in *nfkb1(-/-)* mice lacking NF- κ B p50. Absence of p50 leads to a significant reduction in the number of granulocytic progenitors, CFU-granulocyte, obtained with G-CSF or GM-CSF in vitro and reduces neutrophil production in vivo in response to G-CSF, with preservation of monopoiesis in vitro in response to cytokines or LPS. To gain insight into the mechanism underlying reduced granulopoiesis in the absence of NF- κ B p50, we assessed the expression of several myeloid regulatory proteins in lineage-negative, immature myeloid cells. Although PU.1, C/EBP β , and STAT3 levels were unchanged, C/EBP α protein and RNA levels were reduced ~3-fold in the absence of NF- κ B p50. In addition, NF- κ B p50 and C/EBP α bound the endogenous C/EBP α promoter in a chromatin immunoprecipitation assay, and NF- κ B p50 *trans* activated the C/EBP α promoter, alone or in cooperation with C/EBP α . Despite reduction of C/EBP α , G-CSFR and M-CSFR levels were maintained in total marrow and in lineage-negative cells. Together, these data indicate that acute inflammation not only activates mature myeloid cells, but also stimulates neutrophil production via NF- κ B p50 induction of C/EBP α transcription. *The Journal of Immunology*, 2009, 182: 5757–5762.

Nuclear factor- κ B was first described as an activity in B cells that binds the κ L chain gene enhancer (1, 2). Five NF- κ B family members are found in mammalian cells, as follows: c-Rel, RelA or p65, RelB, NF- κ B1 or p50, and NF- κ B2 or p52. Each possesses a 300-aa Rel homology domain that mediates dimerization, DNA binding, and nuclear localization upon degradation of I κ B. The most abundant and ubiquitous NF- κ B dimers are p50:p65, p50:p50, and p65:p65, with RelB:p52 largely restricted to lymphoid cells. c-Rel, p65, and RelB mediate *trans* activation via their C-terminal domains. p50:p50 homodimers repress transcription via interaction with *bcl-3* and histone deacetylases, but in some contexts are capable of gene activation (3, 4). Inflammatory mediators and pathogen-associated molecular patterns, such as TNF or LPS, are potent mediators of NF- κ B stimulation via the classical pathway of inhibitor of κ B kinase β (IKK β) activation and I κ B degradation, allowing nuclear translocation of p65 and thereby formation of nuclear p50:p65 or p65:p65 dimers.

In mature myeloid cells, NF- κ B and C/EBP β mediate the inflammatory response in part via cooperative activation of the IL-6, IL-8, G-CSF, serum amyloid, ICAM-1, superoxide dismutase, and Mediterranean fever promoters (5–9). C/EBP proteins dimerize via their C-terminal leucine zipper motifs, bind DNA via the adjacent

basic regions (BR),⁴ and activate transcription via N-terminal domains (10, 11). Within hematopoiesis, C/EBP expression is largely restricted to myeloid cells, with C/EBP α most prominent in immature cells and C/EBP β and C/EBP δ induced upon maturation to neutrophils or monocytes (12). Consistent with this expression pattern, C/EBP α ^{-/-} mice demonstrate markedly reduced formation of the granulocyte-monocyte progenitor from the common myeloid progenitor, whereas C/EBP β ^{-/-} retains all the hematopoietic lineages (13, 14).

The BR-leucine zipper domains of C/EBP α and C/EBP β are highly similar and directly interact with the Rel homology domain of p50 or p65 (15, 16). Moreover, we found that mutation of the C/EBP α BR obviates its interaction with p50, but not p65, and that endogenous C/EBP α preferentially binds endogenous p50 compared with p65 in myeloid cells (17). This biochemical link between C/EBP α and p50 prompted us to compare marrow cells from *nfkb1(-/-)* mice lacking p50 with strain-matched controls for their ability to generate myeloid cells in vitro or in vivo and for their expression of C/EBP α . We confirm that absence of p50 does not alter basal numbers of neutrophils (18), but find that *nfkb1(-/-)* mice have reduced in vitro production of the CFU-granulocyte (CFU-G) neutrophil progenitor in response to GM-CSF or G-CSF, reduced in vivo formation of neutrophils in response to G-CSF, and reduced C/EBP α protein and RNA, reflecting the ability of NF- κ B p50 to bind and activate the C/EBP α promoter.

Materials and Methods

Mice and marrow cell culture

Marrow cells obtained from the hind limbs of 8- to 12-wk-old *nfkb1(-/-)* and B6;129P strain-matched control mice (Jackson ImmunoResearch Laboratories) were subjected to red cell lysis with NH_4Cl . For CFU assays, cells were plated directly in methylcellulose (StemCell Technologies) at 20,000 cells/ml in IMDM with 15% heat-inactivated FBS (HI-FBS) and either murine GM-CSF (10 ng/ml), murine M-CSF (10 ng/ml) with murine stem cell factor (SCF; 50 ng/ml; PeproTech), or human G-CSF (100 ng/ml; Amgen) with SCF (50 ng/ml). CFUs were enumerated 8 days later. For *in vivo* cytokine exposure, mice were injected i.p. with 1 μg of G-CSF or GM-CSF daily for 4 days, and blood samples (50 μl) obtained on days 0 and 5 from the facial vein were analyzed for blood counts and white cell differentials using a Hemavet automated counter (MWI). For LPS exposure, cells were cultured in IMDM with 10% HI-FBS with murine SCF (20 ng/ml) and murine Flt3 ligand (FL; 100 ng/ml; PeproTech) with or without *Escherichia coli* 0111:B4 LPS (10 $\mu\text{g}/\text{ml}$; List Biological Laboratories). For protein or RNA preparation from *lin⁻* marrow cells, cells obtained from mice treated 5 days earlier with 5-fluorouracil (150 mg/kg i.p.) were cultured in IMDM with 10% HI-FBS and IL-3, IL-6, and SCF for 5 days, followed by lineage depletion using immunomagnetic beads and a mixture of biotinylated lineage Abs, B220, CD5, Mac-1, Ter¹¹⁹, Gr-1, and 7-4 (StemCell Technologies). Studies with mice have been reviewed and approved by our institutional animal care and use committee.

FACS analysis

To quantify hematopoietic stem cells (HSC), megakaryocyte-erythroid progenitors (MEP), common myeloid progenitor, and granulocyte-monocyte progenitor, marrow was lineage depleted and also depleted for IL-7R by addition of biotin anti-mouse IL-7R α (BD Pharmingen) to the lineage mixture before immunomagnetic depletion. Depleted cells were then stained with FITC anti-CD34, PerCP anti-Sca-1, allophycocyanin anti-*c-kit*, and PE anti-Fc γ R2/III (BD Pharmingen), or IgG control Abs, followed by FACS analysis (19). To quantify common lymphoid progenitors (CLP), lineage-depleted cells were stained with PE anti-IL-7R α , allophycocyanin anti-*c-kit*, and PerCP anti-Sca-1, and then subjected to FACS (19). To assess G-CSFR or M-CSFR expression in total marrow mononuclear cells, cells were stained with biotinylated G-CSF or biotinylated M-CSF, followed by streptavidin-PE, in the absence or presence of 30-fold excess unlabeled G-CSF or M-CSF (20). To assess G-CSFR or M-CSFR expression in lineage-negative marrow cells, cells were stained similarly and also with Alexa Fluor 488-linked mouse lineage Ab mixture (Caltag Laboratories), followed by enumerating PE-staining cells within the Alexa Fluor 488-negative gate.

Western blotting and RNA analysis

Total cellular proteins prepared from lineage-depleted marrow cells were prepared in Laemmli sample buffer, and samples corresponding to 5×10^5 cells were subjected to Western blotting, as described (21), using C/EBP α (14AA), C/EBP β (C19), PU.1 (T-21) (Santa Cruz Biotechnology), STAT3 (79D7) (Cell Signaling Technology), and β -actin (AC-15) (Sigma-Aldrich) Abs. Total cellular RNA was prepared from lineage-depleted cells using TRIzol reagent (Invitrogen). First-strand cDNA was prepared using AMV reverse transcriptase (Promega) and random primers at 42°C for 1 h. Quantitative PCR was conducted using 100 ng of each cDNA using iQ SYBR Green supermix (Bio-Rad). Oligonucleotides used were as follows: CEBPA-F, 5'-TGGATAAGAAGCAACGAG; CEBPA-R, 5'-TCACTGGTCAACTCCAACAC; PU.1-F, 5'-CAGAAGGGCAACCGCAAGAA; PU.1-R, 5'-GCCGCTGAAGTGGTAGGTGA; mS16-F, 5'-CTTGGAGGCTTCATCCACAT; and mS16-R, 5'-ATATTCGGGTCCGTGTGAAG.

Chromatin immunoprecipitation and promoter assays

Ten million mouse whole bone marrow cells were used in each chromatin immunoprecipitation (ChIP) reaction. Cells were incubated with 1% formaldehyde at 37°C for 10 min, and the reaction was quenched with glycine at a final concentration of 0.125 M. Cells were washed twice with ice-cold PBS containing 1 mM PMSF and protease inhibitor mixture (Sigma-Aldrich) and resuspended in 1 ml of ChIP lysis buffer (1% SDS, 10 mM EDTA, 50 mM Tris (pH 8.0), and 1 \times protease inhibitors). Lysates were sonicated on ice using a Branson Sonifier 250, and the chromatin was sheared to 500- to 1,000-bp fragments. Lysates were centrifuged for 10 min at 16,000 \times g to remove insoluble cell debris, and ChIP dilution buffer (167 mM NaCl, 16.7 mM Tris (pH 8.0), 1.1% Triton X-100, 0.01% SDS, 1.2 mM EDTA, and 1 \times protease inhibitors) was added to a final volume of 4 ml. Lysates were precleared with 65 μl of blocked protein A/G-Sepharose beads (Upstate Biotechnology) for 1 h at 4°C. They were briefly cen-

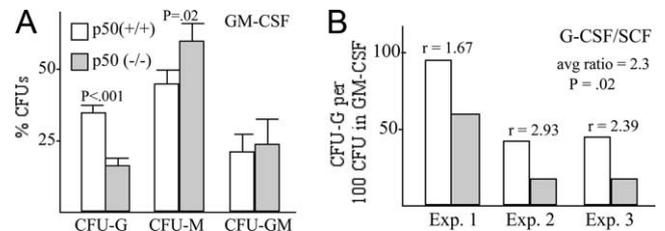

FIGURE 1. Absence of NF- κ B p50 reduces formation of granulocytic progenitors *in vitro*. **A**, Equivalent numbers of mononuclear marrow cells from NF- κ B p50(+/+) or p50(-/-) mice were plated in methylcellulose with GM-CSF. CFU-G, CFU-M, and CFU-GM were enumerated 8 days later. Shown is the percentage of total CFUs represented by each colony type (mean and SE from four determinations). **B**, Mononuclear marrow cells from p50(+/+) or p50(-/-) mice were plated in methylcellulose with G-CSF and SCF, and CFU-G numbers were assessed 8 days later. The number of CFU-G, normalized against total CFU obtained in GM-CSF culture, is shown for three separate experiments. The ratios of normalized CFU-G obtained from p50(+/+) vs p50(-/-) marrow are shown, as is the average ratio.

trifuged, and input was obtained before incubating the resulting supernatant with the antisera against C/EBP α , NF- κ B p50, or rabbit IgG (Santa Cruz Biotechnology) overnight at 4°C with rocking. A total of 60 μl of blocked protein A/G-Sepharose beads was added, followed by incubation at 4°C for 2 h with gentle agitation. The beads were precipitated by centrifugation, and the bead-bound complexes were washed for 5 min in each of the following buffers: low salt wash buffer (0.1% SDS, 1% Triton X-100, 2 mM EDTA, 20 mM Tris (pH 8.0), and 150 mM NaCl), high salt wash buffer (0.1% SDS, 1% Triton X-100, 2 mM EDTA, 20 mM Tris (pH 8.0), and 500 mM NaCl), LiCl wash buffer (0.25 M LiCl, 1% IGEPAL CA-630, 1% sodium deoxycholate, 1 mM EDTA, and 10 mM Tris (pH 8.0)), and two washes in TE (10 mM Tris (pH 8.0) and 1 mM EDTA). DNA-protein complexes were eluted from beads using 200 μl of 1% SDS and 0.1 M NaHCO₃ at room temperature. Cross-links were reversed by adding 10 μl of 4 M NaCl to the eluates and incubation at 65°C overnight. Each sample was treated with RNase and proteinase K, and DNA was isolated with UltraClean DNA Purification Kit (Mo Bio Laboratories). Precipitation of promoters of interest was detected by PCR, and the PCR products were resolved on agarose gels and visualized with ethidium bromide. The following primers were used: CEBPApr-F, 5'-GAACACTTGACTAGAGTGCTC; CEBPApr-R, 5'-CTC GTCCATCGCCTAGG; CEBPAup-F, 5'-CTGTAACCGCAGTGAAGC; and CEBPAup-R, 5'-CTCTAGGGTCCGAGGTCAAG.

NIH 3T3 cells in 60-mm dishes were cotransfected with CMV, CMV-C/EBP α , or CMV-p50 and CEBPA2.3-Luc using Lipofectamine 2000 (Invitrogen), as described (17). pCMV- β Gal was included as an internal control, and samples were collected and assayed 48 h posttransfection. Student's *t* test was used for statistical comparisons.

Results

NF- κ B p50 is required for granulopoiesis *in vitro*

Marrow cells isolated from NF- κ B p50(-/-) mice or strain-matched controls were plated in methylcellulose cultures either with GM-CSF or G-CSF/SCF, and CFU-G, CFU-monocyte (CFU-M), and CFU-granulocyte-monocyte (CFU-GM) myeloid progenitors were enumerated 8 days later (Fig. 1). In GM-CSF culture, CFU-G numbers were significantly reduced in the absence of p50, with a significant increase in CFU-M and no change in CFU-GM. Total CFU obtained in GM-CSF averaged 128/ml plated from p50(+/+) marrow and 110 CFU/ml from p50(-/-) marrow, whereas total CFU-G averaged 44/ml from p50(+/+) marrow and 18/ml from p50(-/-) marrow, and colony sizes were similar between the two genotypes. In G-CSF/SCF, which predominantly yields CFU-G, CFU-G numbers were also consistently reduced in three independent experiments, even when normalized for the mildly reduced total number of CFU obtained with the more permissive CFU-GM cytokine. Reduced CFU-G was not likely due to increased apoptosis, because culture of lineage-negative marrow cells from p50(+/+) or p50(-/-) mice in GM-CSF for 48 h led to 28 vs 27% annexin V-positive cells in one experiment and 17

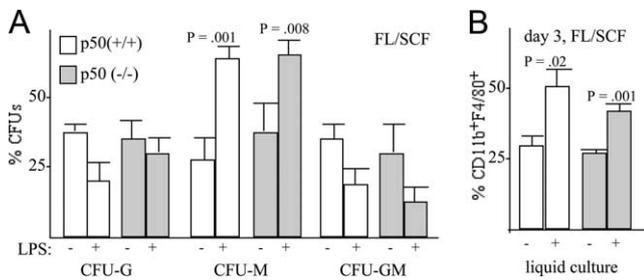

FIGURE 2. Absence of NF- κ B p50 does not reduce induction of monopoiesis by LPS in vitro. *A*, Mononuclear marrow cells from NF- κ B p50(+/+) or p50(-/-) mice were plated in methylcellulose with FL and SCF, without or with LPS. CFU-G, CFU-M, and CFU-GM were enumerated 8 days later. Shown are the percentages of total CFUs represented by each colony type (mean and SE from three determinations). *B*, Cells cultured similarly in liquid culture were subjected to FACS analysis for CD11b and F4/80 on day 3. Shown are the percentages of CD11b⁺F4/80⁺ monocytic cells (mean and SE from three determinations).

vs 15% annexin V-positive cells in a second, independent experiment (data not shown).

NF- κ B p50 is not required for induction of monopoiesis by LPS in vitro

A recent study demonstrated that myeloid progenitors express TLR4 and CD14, and that culture in the presence of FL/SCF and LPS, the ligand for TLR4/CD14, stimulated their development into monocytic cells (22). Because TLR signaling activates NF- κ B, we sought to determine whether absence of NF- κ B p50 impacted on monocytic development in response to LPS. Lineage-negative marrow cells from p50(+/+) or p50(-/-) mice were cultured in IMDM with FBS and FL/SCF, with or without LPS, and cultured either in methylcellulose to assess CFUs or in liquid culture to assess monocyte formation (Fig. 2). Addition of LPS stimulated formation of CFU-M and of CD11b⁺F4/80⁺ monocytes similarly, irrespective of the presence or absence of NF- κ B p50. This finding extends the conclusion that absence of NF- κ B p50 reduces granulopoiesis, but not monopoiesis in vitro. Of note, FACS analysis of wild-type vs p50(-/-) marrow indicated an identical 3.0% Mac1⁺Gr-1⁻ monocytic cells and an average of 61 vs 57% Mac1⁺Gr-1⁺ granulocytic cells in two experiments (data not shown).

NF- κ B p50 is required for granulopoiesis in vivo

We next sought to determine whether NF- κ B p50 is required for G-CSF- or GM-CSF-induced granulopoiesis in vivo. Wild-type p50(+/+) or knockout p50(-/-) mice were injected i.p. with 1 μ g of G-CSF or GM-CSF daily for 4 days. Complete blood counts were obtained on days 0 and 5. Absolute neutrophil counts (ANC) were similar between p50(+/+) and p50(-/-) mice on day 0, as shown in a summary of blood counts obtained from these mice (Fig. 3A). However, G-CSF induced a significantly greater rise in ANC in wild-type mice by day 5, namely 13.0 vs 4.6 thousand/ μ l on average (Fig. 3B). GM-CSF significantly increased the ANC from baseline in wild-type mice, but not in p50(-/-) mice; however, the increase in ANC observed in wild-type mice was not significantly different from that observed in a similar number of p50(-/-) mice, perhaps reflecting the weaker potency of GM-CSF compared with G-CSF in this assay (Fig. 3B). Of note, monocytes were increased in the day 0 blood counts in the p50(-/-) compared with the p50(+/+) mice, lymphocytes were decreased, RBC were slightly reduced, and platelet numbers were similar (Fig. 3A). Overall, these data indicate an increase in monocytes at

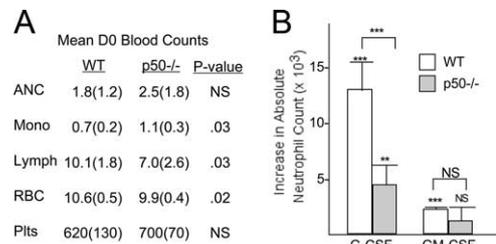

FIGURE 3. Absence of NF- κ B p50 reduces formation of granulocytic progenitors in vivo. *A*, Comparison of mean baseline blood counts in six wild-type (WT) and NF- κ B p50(-/-) mice. ANC, 1000/ μ l; Mono, monocytes, 1000/ μ l; Lymph, lymphocytes, 1000/ μ l; RBC, million/ μ l; Plts, platelets, 1000/ μ l. SEs are shown in parentheses. Each blood cell subset was compared between the two genotypes using Student's *t* test. *B*, NF- κ B p50(+/+) or p50(-/-) mice received 1 μ g of G-CSF or 1 μ g of GM-CSF i.p. daily for 4 days. Shown are the increases in peripheral blood ANC on day 5 compared with day 0 (with mean and SE from six mice for G-CSF and 5 mice for GM-CSF). Significance of the increased ANC on day 5 compared with day 0 in each group was analyzed by paired Student's *t* test (indicated above each error bar), and comparison between the mean ANC increases observed for WT vs p50(-/-) mice injected with each cytokine was obtained using Student's *t* test (indicated above the brackets); ***, $p < 0.001$; **, $p = 0.002$.

baseline without a decrease in granulocytes, the latter potentially due to in vivo compensation, but reduced responsiveness of endogenous myeloid progenitors to G-CSF or GM-CSF, paralleling the in vitro findings.

Absence of NF- κ B p50 has minimal effects on progenitors preceding CFU-G

To gain insight into the role of NF- κ B p50 in early hematopoiesis, we enumerated HSC, common myeloid progenitor, granulocyte-monocyte progenitor, MEP, and CLP in p50(+/+) and p50(-/-) marrow (Fig. 4). Granulocyte-monocyte progenitor numbers were mildly reduced, whereas common myeloid progenitor and HSC were mildly increased, and CLP was also mildly reduced, in the absence of NF- κ B p50. Overall, these changes reflect our finding and the prior demonstration (18) that deletion of NF- κ B p50 does not markedly alter basal production of mature lymphoid, myeloid, erythroid, or megakaryocytic blood cells.

C/EBP α is diminished in immature myeloid cells lacking NF- κ B p50

Total cellular proteins prepared from lineage-negative marrow cells from p50(+/+) and p50(-/-) mice were subjected to Western blotting for C/EBP α , C/EBP β , PU.1, STAT3, and β -actin (Fig. 5, A-C). C/EBP α was diminished 2- to 3-fold in three independent sets of samples, whereas C/EBP β , PU.1, and STAT3 levels were unchanged. Total cellular RNAs prepared from lineage-negative marrow cells from p50(+/+) or p50(-/-) mice were subjected to quantitative RT-PCR analysis for C/EBP α and PU.1, normalized to mouse ribosomal protein S16 (mS16) RNA levels (Fig. 5D). C/EBP α RNA was reduced 3-fold in the absence of NF- κ B p50, whereas PU.1 levels were unchanged. Thus, absence of p50 reduces C/EBP α RNA expression and thereby C/EBP α protein expression in lineage-negative hematopoietic cells obtained from marrow cells that had been cultured with cytokines that favor survival and proliferation of myeloid progenitors (23).

NF- κ B p50 binds and activates the CEBPA promoter

Marrow cells isolated from NF- κ B p50(+/+) or p50(-/-) mice were subjected to ChIP analysis using C/EBP α or p50 antiserum or rabbit Ig, followed by PCR for a 133-bp genomic DNA fragment

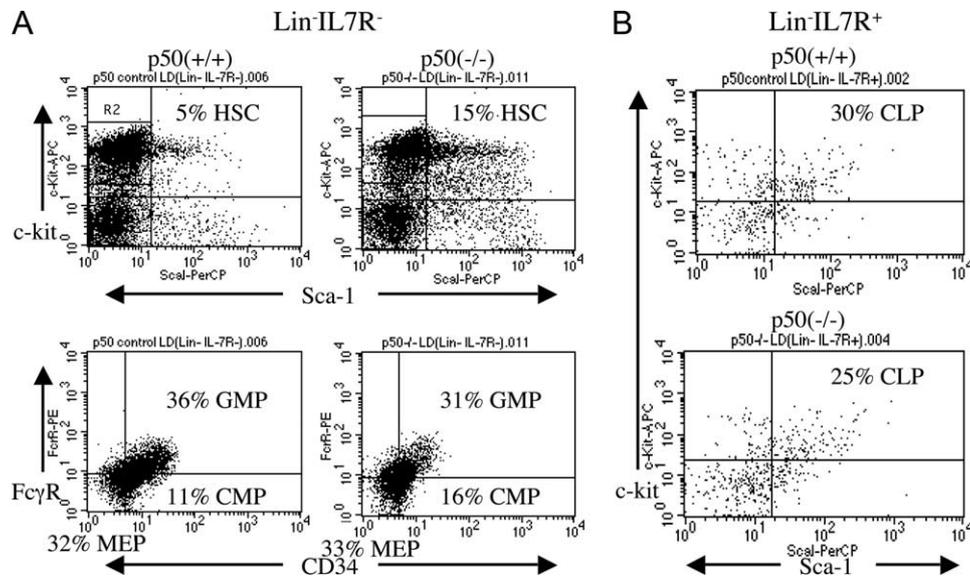

FIGURE 4. Absence of NF- κ B p50 only minimally alters the number of early hematopoietic stem/progenitor cells. *A*, Marrow mononuclear cells from NF- κ B p50(+/+) or p50(-/-) mice were depleted using a lineage-Ab mixture and IL-7R α Ab, followed by staining for Sca-1, *c-kit*, Fc γ RII/III, and CD34 to allow enumeration of Sca-1⁺*c-kit*⁺ HSC, Sca-1⁻*c-kit*⁺Fc γ R⁺CD34⁺ granulocyte-monocyte progenitor, Sca-1⁻*c-kit*⁺Fc γ R^{low}CD34⁺ common myeloid progenitor, and Sca-1⁻*c-kit*⁺Fc γ R^{low}CD34⁻ MEP. Area R2 indicates the Sca-1⁻*c-kit*⁺ cells gated before enumeration of granulocyte-monocyte progenitor, common myeloid progenitor, and MEP in the lower panels. *B*, Lineage-depleted marrow mononuclear cells from NF- κ B p50(+/+) or p50(-/-) mice were stained for IL-7R α , Sca-1, and *c-kit*. IL-7R α ⁺ cells represented 4.0% of p50(+/+) and 4.4% of p50(-/-) total mononuclear cells in the experiment shown. Shown is FACS analysis gating on these populations, to enumerate Sca-1⁺*c-kit*⁺IL-7R α ⁺ CLP. Similar findings were obtained in a second, independent experiment.

centered at -718 bp of the *CEBPA* promoter or for a more upstream 132-bp fragment centered at -1462 bp (Fig. 6A). Interaction of NF- κ B p50 with the endogenous *CEBPA* promoter in wild-type cells was evident. Lack of interaction in knockout cells is expected and provides an additional control indicating lack of nonspecific interaction of the p50 antiserum with other proteins in the vicinity of the *CEBPA* promoter. C/EBP α bound the promoter region in the presence or absence of NF- κ B p50. Finally, neither protein interacted with the more upstream *CEBPA* genomic segment, indicating sufficiency of sonication and localizing these interactions to the vicinity of the more downstream primer set.

CEBPA2.3-Luc, containing 2.3 kb of the murine *CEBPA* promoter linked to a luciferase reporter, was cotransfected with empty CMV vector or with CMV expression plasmids encoding C/EBP α , NF- κ B p50, or both C/EBP α and NF- κ B p50, along with CMV-

β Gal as an internal control (Fig. 6B). Relative to promoter activity in the presence of the empty vector, C/EBP α activated its own promoter 10-fold, as previously described (24), p50 activated the promoter 4-fold, and the combination activated the promoter 28-fold. Together, these data indicate that NF- κ B p50 binds and activates the *CEBPA* promoter cooperatively with C/EBP α . Coexpression of C/EBP α and p50 activated a 341-bp *CEBPA* promoter fragment 12-fold, on average, and activated a 125-bp promoter fragment 7-fold (data not shown), indicating that there may be several relevant κ B *cis* elements, which will require elucidation by future detailed biochemical and functional studies.

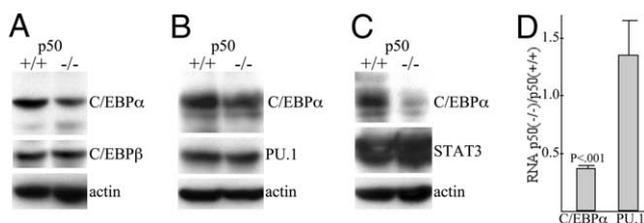

FIGURE 5. C/EBP α protein and RNA levels are reduced in immature myeloid cells lacking NF- κ B p50. *A–C*, Marrow cells from 5-fluorouracil-treated NF- κ B p50(+/+) or p50(-/-) mice were expanded in culture in IL-3, IL-6, and SCF, and then subjected to lineage depletion. Total cellular proteins prepared from the resulting *lin*⁻ population were subjected to Western blotting for C/EBP α , C/EBP β , PU.1, STAT3, and β -actin. Data in each panel were generated from a separate set of mice. *D*, RNA prepared from *lin*⁻ hematopoietic cells obtained using this same experimental protocol from p50(+/+) or p50(-/-) mice were subjected to quantitative RT-PCR analysis for RNAs encoding C/EBP α or PU.1. Shown are the ratios of C/EBP α or PU.1 RNA in p50(-/-) cells: C/EBP α or PU.1 RNA in p50(+/+) cells (means and SE from three determinations).

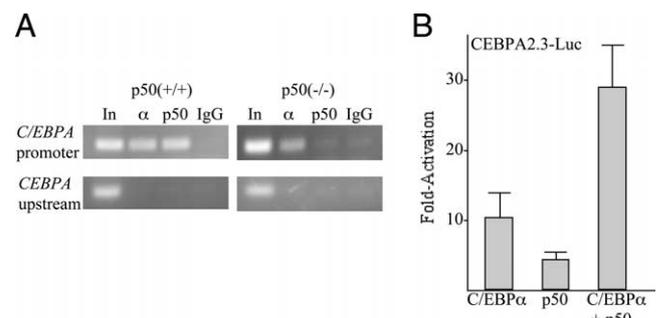

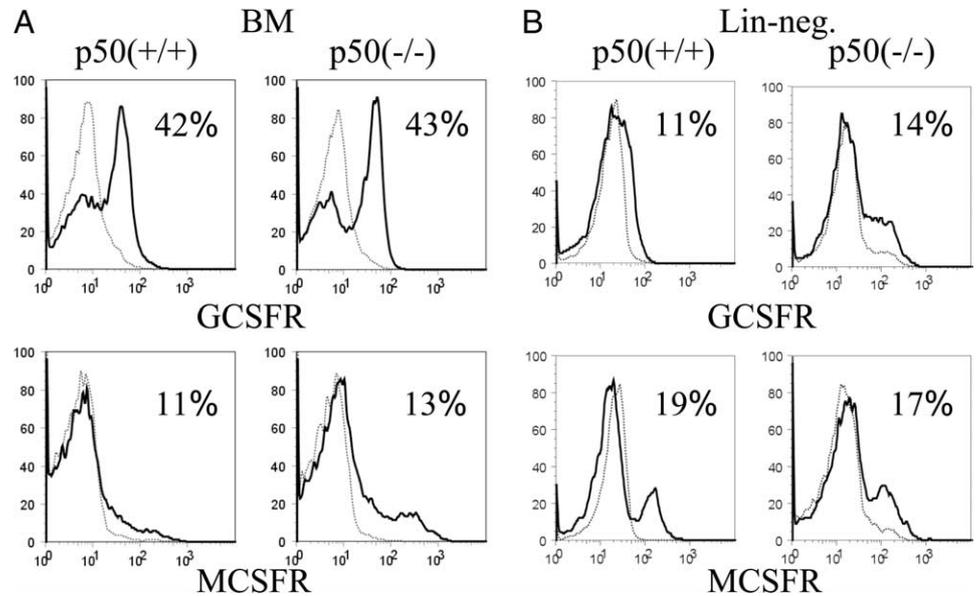

FIGURE 6. NF- κ B p50 binds and activates the *CEBPA* promoter. *A*, Marrow cells from NF- κ B p50(+/+) and p50(-/-) were subjected to ChIP analysis using C/EBP α or p50 rabbit antiserum and control, normal rabbit Ig, followed by PCR for a 133-bp *CEBPA* promoter segment located at -718 bp from the transcription start site and for a 132-bp more upstream *CEBPA* genomic segment located at -1462. Amplified bands were visualized by agarose gel electrophoresis, followed by ethidium bromide staining. *B*, NIH 3T3 cells in 60-mm dishes were transiently transfected with 1.5 μ g of CEBPA2.3-Luc together with 100 ng of pCMV, pCMV-C/EBP α , pCMV-p50, or both pCMV-C/EBP α and pCMV-p50. pCMV- β Gal (10 ng) was included in each transfection as an internal control. Luciferase and β -galactosidase activities were assessed 48 h posttransfection. Shown is fold activation relative to activity obtained with pCMV (mean and SE from three determinations).

FIGURE 7. Absence of NF- κ B p50 does not reduce G-CSFR or M-CSFR expression. **A**, Total marrow mononuclear cells from NF- κ B p50(+/+) or p50(-/-) mice were subjected to FACS analysis for G-CSFR (*top*) or M-CSFR (*bottom*) expression, using biotinylated G-CSF or M-CSF and streptavidin-PE. The darker curves represent staining in the absence of unlabeled G-CSF or M-CSF, and the lighter curves represent staining in the presence of excess cold G-CSF or M-CSF. **B**, Lineage-negative marrow mononuclear cells from NF- κ B p50(+/+) or p50(-/-) mice were analyzed similarly. Representative histograms from triplicate analysis and the percentage of positive cells are shown.

G-CSFR and M-CSFR levels are not reduced in NF- κ B p50(-/-) marrow cells

C/EBP α binds and activates the G-CSFR promoter (25). Having found that absence of NF- κ B p50 reduces C/EBP α protein expression, we therefore considered the possibility that reduced G-CSFR levels in NF- κ B p50(-/-) hematopoietic cells might account for their reduced responsiveness to G-CSF in vitro and in vivo. Total marrow mononuclear cells from NF- κ B p50(+/+) or p50(-/-) mice were subjected to FACS analysis for G-CSFR and also for M-CSFR, another C/EBP α target (26). Both receptors were expressed similarly in the presence or absence of NF- κ B p50 (Fig. 7A). Comparable findings were obtained using cells from a second set of mice (data not shown). G-CSFR and M-CSFR levels were also evaluated lineage-negative p50(+/+) vs p50(-/-) marrow cells (Fig. 7B), and again, similar levels were detected.

Discussion

NF- κ B is central mediator of the inflammatory response. A key finding of this study is that NF- κ B also enables granulopoiesis in response to inflammatory cytokines. NF- κ B p50:p65 and p50:p50 are the most ubiquitous and abundant NF- κ B dimers. NF- κ B p65(-/-) mice display embryonic lethality due to hepatocyte apoptosis (27), an effect rescued by deletion of TNFRI (28). TNFRI(-/-);p65(-/-) murine marrow cells contain normal numbers of neutrophils and monocytes, but their myeloid progenitor numbers and response to inflammatory cytokine stimulation have not been assessed. NF- κ B p50(-/-) mice also generate normal numbers of blood neutrophils, as well as normal numbers of peritoneal macrophages and B and T cell subsets (18); however, our further characterization of hematopoiesis in these mice has uncovered reduced in vitro formation of CFU-G in response to either GM-CSF or G-CSF and reduced in vivo granulopoiesis in response to G-CSF. Moreover, we provide mechanistic insight into the link between NF- κ B p50 expression and granulopoiesis by demonstrating that NF- κ B p50 binds and activates the *CEBPA* promoter, accounting for the striking several-fold reduction in C/EBP α protein and mRNA we detect in immature myeloid cells in the absence of NF- κ B p50. Although the hybrid genetic background of available NF- κ B p50(-/-) mice precludes transplantation into B6;129 strain-matched controls, the similar granulocyte-monocyte progenitor numbers and yet increased response of

wild-type mice to exogenous G-CSF suggest that the granulopoietic defect observed in the absence of NF- κ B p50 is cell intrinsic.

C/EBP α is a key mediator of granulopoiesis. Adult C/EBP α (-/-) mice obtained by deletion of floxed *CEBPA* alleles have a block in the common myeloid progenitor to granulocyte-monocyte progenitor transition, leading to reduced granulocytes and monocytes and their progenitors (14). Interestingly, monoipoiesis at baseline or in response to GM-CSF or LPS was preserved or even mildly increased in NF- κ B p50(-/-) marrow cells in our study, suggesting that the reduction of C/EBP α observed in immature myeloid cells from p50(-/-) mice, to ~33% of normal levels, mainly impacted granulopoiesis. We previously demonstrated that exogenous C/EBP α -estrogen receptor increases monoipoiesis in transduced lineage-negative marrow myeloid progenitors (29), and this effect was preserved in the absence of NF- κ B p50 (data not shown), again indicating that p50 is not critical for monoipoiesis. We assessed marrow progenitors from C/EBP α ^{+/-} murine marrow, which have ~50% of normal C/EBP α , and found no defect in granulopoiesis or monoipoiesis (data not shown), indicating that absence of NF- κ B p50 either further reduces C/EBP α below a threshold critical for optimal granulopoiesis or that NF- κ B has a separate activity beyond regulation of the *CEBPA* gene that contributes to neutrophil production. Perhaps analogous to our findings, it is interesting to note that PU.1^{+/-} mice display normal hematopoiesis, whereas PU.1^{kd/kd} mice, with 20% of normal PU.1 levels due to deletion of a distal enhancer, have greatly reduced monoipoiesis (30). Maintenance of G-CSFR and M-CSFR levels in p50(-/-) marrow cells does not preclude a role for C/EBP α in additional events required for granulopoiesis, because dominant inhibition of C/EBP α to an extent sufficient to diminish G-CSFR expression prevents granulopoiesis even in the presence of exogenous G-CSFR (31). In addition, other cytokine receptor levels might be reduced; we attempted to assess GM-CSFR levels using biotinylated GM-CSF we generated and validated using Ba/F3 cells expressing exogenous receptor, but could not detect GM-CSFR above background levels in total or lineage-depleted marrow cells, suggesting low receptor numbers (data not shown).

NF- κ B p50 directly interacts with C/EBP α to facilitate activation of the genes encoding *blc-2* or *FLIP* (17, 32). Our finding that NF- κ B p50 stimulates C/EBP α expression uncovers an additional layer of cooperation between these two transcription factors. These

two levels of synergy underscore the evolutionary importance of NF- κ B p50:C/EBP α functional interaction. Our finding that C/EBP α binds the endogenous *CEBPA* promoter is consistent with previous in vitro DNA-binding studies (24) and lends further support to the conclusion that C/EBP α autoregulates its own expression. C/EBP α interaction with the *bcl-2* or FLIP promoters is markedly reduced in the absence of NF- κ B p50, whereas C/EBP α binding to its own promoter or to the neutrophil elastase promoter does not require the presence of p50 (32). Thus, C/EBP α regulates genes that control differentiation, such as *CEBPA* and *NE*, independent of p50, but cooperates with p50 to activate genes that inhibit apoptosis. Nevertheless, in this study, we demonstrate functional cooperation between C/EBP α and NF- κ B p50 during granulopoiesis, because NF- κ B p50 directly binds and activates the *CEBPA* promoter. Exogenous C/EBP α enhances monocytic development in lineage-negative wild-type murine progenitors dependent upon zippering with AP-1 proteins (23, 29); the same phenomenon occurs upon transduction of p50(-/-) cell with C/EBP α (data not shown), consistent with a greater role for p50 in granulocyte lineage commitment. The ability of directed C/EBP α homodimers to rescue granulopoiesis in p50(-/-) progenitors will be pursued in future experiments.

The finding that granulocyte-monocyte progenitors express TLR2 and TLR4 provides one avenue for stimulation of myeloid cell production during an inflammatory response (22), and in fact those investigators demonstrate that LPS stimulates monopoiesis. Absence of NF- κ B p50 did not blunt this response in our study, suggesting a role for additional signaling molecules activated by TLR4. Future investigations may find that ligation of additional TLRs stimulates granulopoiesis, with a specific role for NF- κ B p50.

Overall, this study indicates that NF- κ B p50 activation by inflammatory cytokines induces C/EBP α to stimulate emergency granulopoiesis. Future investigations will seek to identify additional regulatory proteins that cooperate in this process to gain additional insight into mechanisms of granulopoiesis under basal and stress conditions.
