Ubiquitylation of an Internalized Killer Cell Ig-Like Receptor by Triad3A Disrupts Sustained NF-κB Signaling

S. M. Shahjahan Miah, Amanda K. Purdy, Nicholas B. Rodin, Alexander W. MacFarlane, IV, Jennifer Oshinsky, Diana A. Alvarez-Arias, and Kerry S. Campbell

Killer cell Ig-like receptor (KIR) with two Ig-like domains and a long cytoplasmic domain 4 (2DL4; CD158d) is a unique KIR expressed on human NK cells, which stimulates cytokine production, but mechanisms regulating its expression and function are poorly understood. By yeast two-hybrid screening, we identified the E3 ubiquitin ligase, Triad3A, as an interaction partner for the 2DL4 cytoplasmic domain. The protein interaction was confirmed in vivo, and Triad3A expression induced polyubiquitylation and degradation of 2DL4. Overexpression of Triad3A selectively abrogated the cytokine-producing function of 2DL4, whereas Triad3A short hairpin RNA reversed ubiquitylation and restored cytokine production. Expression of Triad3A in an NK cell line did not affect receptor surface expression, internalization, or early signaling, but significantly reduced receptor turnover and suppressed sustained NF-κB activation. 2DL4 endocytosis was found to be vital to stimulate cytokine production, and Triad3A expression diminished localization of internalized receptor in early endosomes. Our results reveal a critical role for endocytosed 2DL4 receptor to generate sustained NF-κB signaling and drive cytokine production. We conclude that Triad3A is a key negative regulator of sustained 2DL4-mediated NF-κB signaling from internalized 2DL4, which functions by promoting ubiquitylation and degradation of endocytosed receptor from early endosomes. The Journal of Immunology, 2011, 186: 2959–2969.
tion have been widely appreciated, whereby internalized receptors can be sorted to degradation pathways mediated by lysosomes or the proteasome.

Conjugation with ubiquitin (Ub) is a common mechanism for tagging proteins for trafficking, degradation, and signaling (16, 17). Ubiquitylation of transmembrane proteins can promote either the initial step of internalization and/or subsequent sorting from the early endosome to degradation in lysosomes or the proteasome. Ub peptides are covalently attached to lysine residues on target proteins through substrate-specific recognition by distinct Ub-protein ligases, known as E3 subunits.

Using a yeast two-hybrid approach, we have identified the RING-finger-containing E3 Ub ligase, Triad3A, as a 2DL4 cytoplasmic binding partner. We show that Triad3A interacts with 2DL4 and induces ubiquitylation and degradation of the receptor, although surface receptor expression is unchanged. Our data also show that Triad3A suppresses 2DL4-mediated cytokine production, accumulation in early endosomes, and sustained NF-kB activation, but does not affect early signaling events, suggesting that Triad3A is a critical regulator of late-term 2DL4 signaling at an intracellular site.

**Materials and Methods**

**Cells and culture**

The KHYG-1 cell line [obtained from Health Science Research Resources Bank, Japan Health Sciences Foundation; JCRB0156 (18)] was cultured in IL-2–containing α-MEM medium as previously described (5, 12). HEK-293T cells (kindly provided by Dr. Shao Cong-Sun, M.D. Anderson Cancer Center) were cultured in DMEM plus 10% FBS, 100 U/ml penicillin, and 100 μg/ml streptomycin (Invitrogen). The retrovirus producing Phoenix-Ampho cells were cultured as described (19). Sorted primary CD56+CD3ε+ CD56+CD3ε+ knockout (KO) mice were provided by Dr. T.-H. Chuang (Scripps Institute, La Jolla, CA); HRP-conjugated goat anti-mouse IgG and goat anti-rabbit IgG from Abcam or kindly provided by Dr. L. Heasley (University of Colorado, Denver, CO).

**Plasmids and reagents**

CD56+CD3ε+ CD56+CD3ε+ knockdown (KD) transduction of KHYG-1 cells was previously described (19). Transduced cells were blocked with 50 μg/ml unlabeled anti-FLAG polyclonal Ab and RAPID gold conjugated anti-FLAG mAb for 1 h on ice, washed twice, kept at 37˚C for the indicated times, stained with PE-conjugated streptavidin for 1 h on ice, washed, and analyzed by flow cytometry.

**Immunoprecipitation and immunoblotting**

Cell lysate preparation in 1% Triton X-100 buffer, immunoprecipitation, SDS-PAGE, and immunoblotting were performed as previously described (12). For two-dimensional gel electrophoresis, proteins were solubilized with sample buffer (7 M urea, 2 M thiourea, 4% CHAPS), and 100 μg of protein was applied to each pH (3–10) NL isoelectric focusing strip, focused on a PROTEAN IEF Cell (Bio-Rad, Hercules, CA) (25), separated on 10% SDS-PAGE, transferred to polyvinylidene difluoride membrane, and immunoblotted.

**Quantitative RT-PCR**

Total RNA was isolated from the RNeasy Kit (Qiagen, Valencia, CA), and quantitative RT-PCR (qRT-PCR) was performed using TaqMan PCR reagents and Triad3- or GAPDH-specific primers and probes on a 7500 Real-Time PCR system (all from Applied Biosystems, Foster City, CA). The mRNA copy numbers of a particular gene in each sample were normalized to the mRNA copy number of the housekeeping gene GAPDH in that sample.

**Assay of NK activity**

JNK was assayed using GST-c-Jun as a substrate to measure the phosphorylation by JNK in an in vitro kinase assay (24). Briefly, GST-c-Jun (aa 1–79) was isolated on glutathione-agarose (Pierce) and used to precipitate JNK from lysates of stimulated NK cells. After immunoprecipitation, JNK-GST–c-Jun complexes were suspended in 40 mM Tris-Cl (pH 7.5), 0.1 mM sodium orthovanadate, 10 mM MgCl2, 1 mM EDTA, and 20 μM ATP, incubated for 20 min at 30°C while mixing the assay components by frequent vortexing, denatured with 3% Laemmli buffer, separated by SDS-PAGE, transferred to polyvinylidene difluoride membrane, and immunoblotted.

**Cellular assays**

For cytokine/chemokine assays, KHYG-1 cells transfected with FLAG-2DL4 (aa 858–1032) were cultured for 24 h in a 96-well plate containing plate-bound mAb, and culture supernatants were assayed using ELISA kits for IL-8, MIP1α (Pierce Biotechnology), or IFN-γ (BD Pharmingen) as previously described (12).

**KIR2DL4 internalization assay**

The internalization assay was adapted from previously established assays (20, 25, 26). Cells were stained with 10 μg/ml biotinylated anti-FLAG mAb for 1 h on ice, washed twice, kept at 37°C for the indicated times, stained with PE-conjugated streptavidin for 1 h on ice, washed, and analyzed by FACS. The percent internalization was calculated from mean fluorescence intensity (MFI) of staining at the indicated time point (t) compared with time zero (0) using the calculation: % internalization = 100 − ([MFI t’ min/MFI 0’t min]100).

**KIR2DL4 turnover assay**

2DL4 surface turnover was assayed as previously described (20, 27). Briefly, cells were blocked with 50 μg/ml unlabeled anti-FLAG polyclonal Ab (Sigma-Aldrich) in HBSS plus 1% FBS for 40 min at 4°C, washed, and

![Image](http://www.jimmunol.org/content/176/10/5956/F1.large.jpg)
incubated in α-MEM at 37°C. Cell aliquots were stained on ice with biotinylated anti-FLAG mAb and PE-streptavidin, analyzed on a FACScan (BD Biosciences), and evaluated with FlowJo software (Tree Star). The percent turnover of 2DL4 staining = 100 × (MFI_{[exp]} − MFI_{[blocked]})/(MFI_{[blocked]} − MFI_{[total]}) in which MFI_{[exp]} is 2DL4 staining at the indicated time, MFI_{[blocked]} is staining of untreated cells and MFI_{[blocked]} is staining cells blocked with unlabeled Ab and kept at 4°C. In some experiments, cells were treated with 50 μg/ml cycloheximide during blocking and throughout the assay (20).

**EMSA analysis**

Nuclear extracts were prepared by using a nuclear extraction kit (Panomics). For EMSA, the NF-κB consensus oligonucleotide 5′-GGGGACTTTCCC-3′ (Santa Cruz Biotechnology) was end-labeled with [γ-^32P]ATP (Perkin Elmer) and T4 polynucleotide kinase (Promega) and purified using Microspin G-50 columns (GE Healthcare). Nuclear extracts were mixed with the labeled probe in 20 μl buffer (3.75 mM HEPES [pH 7.6], 1.5% v/v glycerol, 0.5 mM DTT, 0.015 mM EDTA, 0.5 μg polyinosinic:polycytidylic acid [Roche]) and incubated at room temperature (RT) for 30 min. For supershifts, Abs to the p65 subunit of NF-κB (Santa Cruz Biotechnology) were added to extracts for 30 min prior to addition of radiolabeled oligonucleotide. DNA–protein complexes were separated on 5% nondenaturing PAGE and autoradiographed.

**Immunoblotting for expression of Triad3 and GAPDH in total lysates of primary NK cells, KHYG-1 NK cell line, NK-92 NK cell line, NKL NK cell line, 293T cells, and KHYG-1, primary NK, and 293T cells. Results from two experiments were normalized to GAPDH mRNA levels in each cell type and expressed as fold difference as compared with the amounts detected in KHYG-1 cells, which were set at a relative value of 1.**

**Results**

**Identification of Triad3A as a 2DL4-interacting protein by yeast two-hybrid screening**

Previous work from our laboratory and others (8, 12) suggested that the cytoplasmic domain of 2DL4 might interact directly with...
other proteins to mediate intracellular signaling. Therefore, we used the yeast two-hybrid system to identify proteins that interact with the 2DL4 cytoplasmic domain. Five positive clones isolated from the library screen growth assay were also found to interact with the cytoplasmic domain in a secondary assay for β-galactosidase production, as shown in Fig. 1A. All five clones contained cDNA encoding the C-terminal sequence of human Triad3 (also known as ZIN or RNF216), which exhibits E3 Ub ligase activity (29, 30). The 2DL4-interacting sequence (aa 507–866) contained the two TRIAD (two RING finger and DRIL) domains and the IBR (in between RING) region (Fig. 1B). Triad3 is one of six mRNA splice variants (designated Triad3 and Triad3A-E), all of which include the common C-terminal domain isolated in our screen. Subsequently, we focused our studies on Triad3A, which is one of the largest and most abundantly expressed forms (29).

Previous work has shown that Triad3A interacts with several TLRs, promotes their degradation by ubiquitylation, and inhibits their function (29). Triad3A also acts as a negative regulator in TNF-α receptor signaling by interacting with and inducing ubiquitylation and degradation of RIP-1 kinase, as well as degradation of the TIRAP and TRIF adaptors, all of which are important for initiating NF-κB signaling (30). Recently, it has been shown that Triad3A also targets TNFR-associated factor (TRAF) 3 for ubiquitylation and degradation and negatively regulates the RIG-I/MAVS pathway (31). These results suggested that Triad3A might similarly suppress 2DL4 functions.

Triad3A interacts with 2DL4 in 293T cells to promote polyubiquitylation and degradation

We tested whether Triad3A interacts with 2DL4 and promotes its degradation by cotransfecting cDNAs encoding both proteins into 293T cells. Cotransfection of Triad3A dramatically diminished the total level of 2DL4 protein detected in 293T cell lysates (Fig. 2A), which is consistent with the previously reported impacts on TLRs (29). To test whether Triad3A associates with 2DL4, we cotransfected 293T cells with increasing amounts of Triad3A cDNA and a constant amount of 2DL4 cDNA. Immunoprecipitation of the receptor showed progressively decreased 2DL4 protein recovery that correlated with increasing amounts of Triad3A protein expression and coordinate increases in the amount of Triad3A coimmunoprecipitating with the receptor (Fig. 2B).

FIGURE 2. Triad3A promotes polyubiquitylation and degradation of 2DL4 in 293T cells. A, Coexpression of Triad3A reduces 2DL4 expression in 293T cells. 293T cells were transfected with FLAG-2DL4 and FLAG-Triad3A, lysed 48 h later, separated by SDS-PAGE, and immunoblotted with anti-FLAG mAb. B, Triad3A associates with and induces degradation of 2DL4 protein. 293T cells were cotransfected with indicated amount of FLAG-Triad3A and 1 μg FLAG-2DL4–encoding plasmids, lysed 48 h later (lysates in top panel), and 2DL4 immunoprecipitates (IP in bottom panel) were immunoblotted with anti-FLAG mAb. C, Triad3A induces ubiquitylation of 2DL4. 293T cells were transfected with indicated cDNAs, lysed 48 h later, immunoprecipitated with anti-2DL4 mAb, and analyzed for Ub by anti-HA immunoblotting. D, Structure of WT-2DL4 and the 5R-2DL4 constructs. E, Direct polyubiquitylation of lysines in the cytoplasmic domain of 2DL4 by Triad3A. 293T cells were transfected with indicated combinations of cDNAs, lysed 48 h later, immunoprecipitated with anti-2DL4 mAb, and immunoblotted for Ub by anti-HA Ab. Immunoprecipitates and lysates were also probed with anti-FLAG mAb to detect Triad3A (bottom panel). F, Analysis of lysine-dependent ubiquitylation of 2DL4 by 2D gel electrophoresis. 293T cells were transfected with FLAG-Triad3A, HA-Ub, and FLAG-WT-2DL4 (left panel) or FLAG-5R-2DL4 (right panel), lysed 48 h later, immunoprecipitated with anti-2DL4 mAb, separated by two-dimensional gel electrophoresis (isoelectric focusing/SDS-PAGE), and immunoblotted for Ub with anti-HA Ab. K, Lys; R, Arg; TM, transmembrane.
We next tested whether Triad3A also induces the ubiquitylation of 2DL4 by transfecting FLAG-tagged Triad3A, FLAG-2DL4, and HA-tagged Ub (HA-Ub) cDNAs into 293T cells. As shown in Fig. 2C, Triad3A induced strong polyubiquitylation of 2DL4 when all three cDNAs were coexpressed. Mutation of the five cytoplasmic lysines in 2DL4 (Fig. 2D) to arginine (5R-2DL4 mutant) abrogated the polyubiquitylation of 2DL4 (Fig. 2E), indicating direct polyubiquitylation of at least one of these lysines by Triad3A. Two-dimensional gel electrophoresis demonstrated the extensive degree of direct 2DL4 polyubiquitylation that was disrupted by lysine mutation (Fig. 2F).

**Triad3A suppresses KIR2DL4 function in 293T cells**

A previous report showed that 2DL4 transfection into 293T cells resulted in spontaneous IL-8 production (8), suggesting that these cells may contain a ligand that engages the receptor to result in productive signal transduction. Thus, we speculated that 2DL4-mediated IL-8 production might be impacted by cotransfection with Triad3A. As shown in Fig. 3A, 2DL4 transfection indeed promoted spontaneous IL-8 production in 293T cells, and Triad3A cotransfection essentially eliminated this IL-8 production, suggesting that Triad3A-induced ubiquitylation and degradation of 2DL4 profoundly inhibits receptor function.

To demonstrate the direct involvement of Triad3A in regulating 2DL4 function, we used shRNA to knockdown expression in 293T cells. We prepared three shRNA expression constructs targeting different regions of Triad3A. Both shRNA1 and shRNA3 efficiently knocked down the cDNA-driven expression of Triad3A protein by >90% (Fig. 3B), whereas shRNA2 was ineffective. We then tested whether knockdown of Triad3A will reverse Triad3A-mediated 2DL4 ubiquitylation and restore receptor function. As expected, cotransfection of shRNA1 or shRNA3 nearly abolished 2DL4 ubiquitylation (Fig. 3B), whereas shRNA2 had no effect. Furthermore, shRNA1 and shRNA3 efficiently reversed the inhibition of 2DL4-mediated IL-8 production by Triad3A in 293T cells (Fig. 3C), demonstrating direct involvement of

---

**FIGURE 3.** Triad3A suppresses 2DL4-mediated production of IL-8 in 293T cells. **A**, Triad3A coexpression suppresses 2DL4-mediated IL-8 production. 293T cells were transfected with FLAG-2DL4 ± FLAG-Triad3A cDNAs and tested 48 h later for IL-8 secretion by ELISA. Results are mean ± SD of single assays from eight experiments. **B**, Triad3A knockdown reduces 2DL4 ubiquitylation in 293T cells. 293T cells were transfected with cDNAs encoding combinations of FLAG-2DL4, FLAG-Triad3A, HA-Ub, and one of three shRNAs targeting Triad3A. After 48 h, cells were lysed and 2DL4 immunoprecipitates (top panel) or cell lysates (bottom panels) were immunoblotted as indicated. **C**, 2DL4-mediated IL-8 production was restored by Triad3A knockdown. 293T cells were transfected with indicated combinations of FLAG-2DL4, FLAG-Triad3A, and one of the shRNA constructs and tested 48 h later for IL-8 production by ELISA. Results are mean ± SD of a single assay from three experiments. **D**, Knockdown of endogenous Triad3A significantly enhanced 2DL4-mediated IL-8 production in 293T cells. 293T cells were transfected with shRNA3 and stably transfected cells were selected by treating with puromycin (2 μg/ml) for 7 d. The shRNA transfectants and 293T parent cells were then transfected with 2DL4 and assayed 48 h later for IL-8 secretion by ELISA (top panel). Results are mean ± SD of a single assay from three experiments. Lysates from 293T transfectants were immunoblotted with anti-Triad3A and anti-GAPDH to assess knockdown efficiency (bottom panel). Note that 10-fold less lysate was added for the Triad3A transfected sample (lane 3).
Triad3A in regulating 2DL4 function. To further confirm that endogenous levels of Triad3A impact 2DL4 function, we found that knocking down expression levels of endogenous Triad3A in 293T cells with shRNA3A significantly enhanced 2DL4-mediated IL-8 production (Fig. 3D), demonstrating the importance of physiological levels of Triad3A in controlling 2DL4 function.

2DL4-mediated cytokine production is suppressed by Triad3A in an NK cell line

We and others have previously reported that engagement of 2DL4 with plate-bound Ab stimulates the production of cytokines and chemokines in NK cell culture supernatants (2, 9, 12). To test the effect of Triad3A expression on the 2DL4-mediated induction of cytokine production, we engineered the KHYG-1 NK cell line to stably express FLAG-2DL4 alone or in combination with Triad3A by retroviral transduction. As in 293T cells, total 2DL4 protein expression in NK cell lysates was significantly suppressed by Triad3A coexpression, indicating that 2DL4 is degraded by ubiquitylation (Fig. 4A). We were surprised to find, however, that 2DL4 surface expression on the NK cell line was unaffected by Triad3A expression (Fig. 4B), indicating that Triad3A decreases the intracellular pool of 2DL4 while not impacting the level of surface receptor. Next, we tested the effect of Triad3A coexpression on the 2DL4-mediated activation of cytokine production in NK cells. KHYG-1 cells expressing FLAG-2DL4 alone or in combination with Triad3A were either left unstimulated or stimulated with plate-bound anti-FLAG mAb or anti-NKp44 mAb to ligate another NK cell activating receptor. Consistent with results in 293T cells, Triad3A coexpression significantly suppressed 2DL4-mediated production of IL-8, MIP-1α, and IFN-γ by the NK cell line, whereas Nkp44-mediated cytokine production was unaffected (Fig. 4C–E). Our data demonstrate that expression of Triad3A selectively and efficiently suppresses 2DL4 function in NK cells, and suppression correlates with substantially decreased total levels of intracellular 2DL4, whereas surface receptor expression levels are unaffected.

Triad3A suppresses 2DL4-mediated late-term NF-κB activation without affecting early signaling

In addition to stimulating cytokine production, 2DL4 cross-linking activates MAPK (phosphorylation of JNK, ERK, and p38) and NF-κB (phosphorylation of IKKβ and IκBα, and degradation of IκBα) (12). We also previously showed that all of these pathways are critical for downstream cytokine production in NK cells, and stimulation of p38 and ERK are upstream of NF-κB activation (12). Therefore, we tested whether exogenous Triad3A expression in KHYG-1 cells regulates 2DL4-mediated activation of MAPK and NF-κB. To our surprise, Triad3A expression did not suppress 2DL4-mediated phosphorylation of ERK or p38 (Fig. 5A), and the activation of JNK was unaffected (Fig. 5B). In addition, Triad3A expression did not affect early phosphorylation of IκKα/β, which is an upstream kinase of the NF-κB activation cascade (Fig. 6A). The canonical NF-κB pathway culminates in translocation of the p65 subunit to the nucleus, where it binds to specific DNA sequences to regulate gene transcription. Therefore, we further tested the effect of Triad3A coexpression on 2DL4-mediated activation of NF-κB by EMSA. Our results show that expression of Triad3A in KHYG-1 cells consistently diminished the maintenance of p65 DNA binding activity in response to 2DL4 engagement, especially at later time points (Figs. 6B, 6C). To further confirm the negative impact of Triad3A on sustained NF-κB activation, we measured activity in 293T cells 48 h posttransfection with 2DL4 ± Triad3A using a luciferase reporter assay. Our data demonstrated that Triad3A expression nearly abolishes 2DL4-mediated activation of NF-κB (Fig. 6D). In conclusion, Triad3A does not affect the 2DL4-mediated early activation of MAPK and IKKα/β, but suppresses sustained activation of NF-κB, demonstrating that only late-term signaling is disrupted by Triad3A.
Triad3A inhibits 2DL4 turnover without affecting receptor internalization

Endocytosis is a critical event influencing the turnover, signal transduction, and biological functions of cell-surface receptors. Internalized receptors generally enter Rab5⁺ early endosomes, where some receptors are sorted to lysosome and proteasome compartments for degradation, whereas others can be recycled back to the cell surface (15, 32).

Previous work showed that vesicle-mediated endocytosis is required to transport 2DL4 to the Rab5⁺ early endosomal compartment, because expression of a dominant-negative (DN) form of dynamin inhibited 2DL4 internalization to that location (8). Dynamins are large GTPases that facilitate vesicle invagination and scission during endocytic processes, especially involving clathrin-coated vesicles or caveolae (33). In view of the DN-dynamin impact and our observations that Triad3A expression in KHYG-1 cells selectively abolished 2DL4-mediated cytokine production without altering surface expression or early signaling events, we speculated that the E3 Ub ligase might be disrupting intracellular receptor trafficking to prevent sustained NF-κB signaling and achieve cytokine production. Therefore, we examined whether Triad3A expression affects 2DL4 endocytosis, turnover, and intracellular localization in response to receptor ligation.

First, we found that Triad3A expression does not affect receptor endocytosis over time in KHYG-1 cells (Fig. 7A). Consistent with our previous findings, these data further demonstrate that Triad3A does not impact 2DL4 at the cell surface. Next, we tested whether 2DL4 receptor turnover back to the cell surface was affected by Triad3A expression. Although 2DL4 was efficiently turning over in KHYG-1 cells expressing the receptor alone, Triad3A expression significantly suppressed receptor turnover (Fig. 7B). This result was consistent when performed in the presence of the protein synthesis inhibitor cycloheximide (data not shown), indicating that Triad3A expression is not suppressing 2DL4 surface expression derived from de novo synthesis, but is instead suppressing the recycling of internalized 2DL4 back to the cell surface. Therefore, we hypothesize that Triad3A expression promotes the ubiquituation of the majority of internalized 2DL4, which is shuttled to the proteasome or lysosome for degradation, thereby preventing recycling back to the cell surface.

Triad3A disrupts 2DL4 localization with Rab5⁺ early endosomes

We next determined whether vesicle-mediated endocytosis is necessary for 2DL4 to stimulate the production of IL-8 in 293T cells. As shown in Fig. 7C, cotransfection of 2DL4 in combination with DN-dynamin nearly abolished 2DL4-mediated IL-8 production, indicating a requirement for receptor internalization to trigger cytokine production. We further observed that the pharmacological dynamin inhibitor cycloheximide (data not shown), indicating that Triad3A expression is not suppressing 2DL4 surface expression derived from de novo synthesis, but is instead suppressing the recycling of internalized 2DL4 back to the cell surface. Therefore, we hypothesize that Triad3A expression promotes the ubiquituation of the majority of internalized 2DL4, which is shuttled to the proteasome or lysosome for degradation, thereby preventing recycling back to the cell surface.

Triad3A inhibits 2DL4 turnover without affecting receptor internalization

Endocytosis is a critical event influencing the turnover, signal transduction, and biological functions of cell-surface receptors. Internalized receptors generally enter Rab5⁺ early endosomes, where some receptors are sorted to lysosome and proteasome compartments for degradation, whereas others can be recycled back to the cell surface (15, 32).

Previous work showed that vesicle-mediated endocytosis is required to transport 2DL4 to the Rab5⁺ early endosomal compartment, because expression of a dominant-negative (DN) form of dynamin inhibited 2DL4 internalization to that location (8). Dynamins are large GTPases that facilitate vesicle invagination and scission during endocytic processes, especially involving clathrin-coated vesicles or caveolae (33). In view of the DN-dynamin impact and our observations that Triad3A expression in KHYG-1 cells selectively abolished 2DL4-mediated cytokine production without altering surface expression or early signaling events, we speculated that the E3 Ub ligase might be disrupting intracellular receptor trafficking to prevent sustained NF-κB signaling and achieve cytokine production. Therefore, we examined whether Triad3A expression affects 2DL4 endocytosis, turnover, and intracellular localization in response to receptor ligation.

First, we found that Triad3A expression does not affect receptor endocytosis over time in KHYG-1 cells (Fig. 7A). Consistent with our previous findings, these data further demonstrate that Triad3A does not impact 2DL4 at the cell surface. Next, we tested whether 2DL4 receptor turnover back to the cell surface was affected by Triad3A expression. Although 2DL4 was efficiently turning over in KHYG-1 cells expressing the receptor alone, Triad3A expression significantly suppressed receptor turnover (Fig. 7B). This result was consistent when performed in the presence of the protein synthesis inhibitor cycloheximide (data not shown), indicating that Triad3A expression is not suppressing 2DL4 surface expression derived from de novo synthesis, but is instead suppressing the recycling of internalized 2DL4 back to the cell surface. Therefore, we hypothesize that Triad3A expression promotes the ubiquituation of the majority of internalized 2DL4, which is shuttled to the proteasome or lysosome for degradation, thereby preventing recycling back to the cell surface.

Triad3A disrupts 2DL4 localization with Rab5⁺ early endosomes

We next determined whether vesicle-mediated endocytosis is necessary for 2DL4 to stimulate the production of IL-8 in 293T cells. As shown in Fig. 7C, cotransfection of 2DL4 in combination with DN-dynamin nearly abolished 2DL4-mediated IL-8 production, indicating a requirement for receptor internalization to trigger cytokine production. We further observed that the pharmacological dynamin inhibitor, dynasore (34), similarly blocked 2DL4-mediated IL-8 production in 293T cells in a dose-dependent manner (Fig. 7D). Although DN-dynamin expression was toxic to KHYG-1 cells, we found that dynasore also suppressed IL-8 production in response to engaging 2DL4 in the NK cell line without affecting production of the cytokine upon engaging NKp44 (Fig. 7E). Our results demonstrate that 2DL4-mediated cytokine production requires receptor internalization, which is consistent with recent work by Rajagopalan et al. (13).

Previous evidence indicates that 2DL4 localization into the Rab5⁺ early endosomes is a critical step to induce cytokine production (8, 13), so we tested whether Triad3A expression alters the localization of 2DL4 to early endosomes after 2DL4 ligation in KHYG-1 cells. Cells expressing myc-tagged 2DL4 either with or
luciferase activity in lysates was assayed 48 h later. Results are mean ± SD of relative units NF-κB activity from six experiments. NS, nonspecific band.

FIGURE 6. Triad3A expression suppresses sustained activation of NF-κB in response to 2DL4 ligation. A, KHYG-1 cells transduced with FLAG-2DL4 ± FLAG-Triad3A (day 2 after IL-2 culture) were stimulated with soluble anti-FLAG mAb (M2; 10 μg/ml) for the indicated time or PMA (P; 10 nM) + ionomycin (I; 1 μM) (10 min). Cell lysates were immunoblotted with anti–phospho-IKKα/β (pIKKα/β) and anti-GAPDH. B, 2DL4 ligation-induced nuclear DNA binding activity of NF-κB-p65 complexes. KHYG-1 cells expressing FLAG-2DL4 ± FLAG-Triad3A were stimulated with soluble anti-FLAG mAb (10 μg/ml) for indicated time or PMA and ionomycin (P/I) for 120 min. Nuclear extracts were preincubated with radiolabeled dsNF-κB oligonucleotide probe and analyzed on nondenaturing PAGE. The last lane shows anti-p65 Ab supershift (ss) analysis of a PMA/ionomycin-stimulated extract. Results are representative of at least three experiments. C, The p65 DNA binding band in B was quantified with ImageJ software (National Institutes of Health), and plot shows percent binding activity compared with unstimulated control at time zero (= 100%) from B. D, Triad3A expression suppressed 2DL4-stimulated NF-κB luciferase reporter activity. 293T cells were transfected with NF-κB renilla luciferase reporter plasmid in combination with FLAG-2DL4 ± FLAG-Triad3A cDNAs and luciferase activity in lysates was assayed 48 h later. Results are mean ± SD of relative units NF-κB activity from six experiments. NS, nonspecific band.

without Triad3A were surface stained with anti-myc Ab and fluorophore-conjugated secondary Ab, incubated at 37°C for 1 to 2 h to allow for receptor internalization, fixed, permeabilized, and stained for the early endosomal markers Rab5 (Fig. 8A, 8B, Supplemental Fig. 1) or EEA1 (Fig. 8C, 8D, and Supplemental Fig. 2). When 2DL4 was expressed alone, ~15% of the receptor entered the Rab5/EEA1 compartment under these cross-linking conditions (Fig. 8, Supplemental Figs. 1, 2), although the fraction accumulating in the early endosomes with our cellular system was significantly lower than shown in previous work by Rajagopal et al. (8, 13). Nonetheless, when cells coexpressed Triad3A, the 2DL4 appeared to be distributed more at the periphery of the cells or in cellular extensions, and only ~5% of the receptor colocalized with Rab5 or EEA1 (Fig. 8, Supplemental Figs. 1, 2). Taken together, our data demonstrate that Ab-engaged 2DL4 is endocytosed, and some localizes to Rab5+/EEA1+ early endosomes. However, this endosomal localization is significantly diminished by coexpression of Triad3A (Fig. 8C, 8D), which, according to our previous evidence, promotes polyubiquitylation of 2DL4 and trafficking to the proteasome or lysosome for degradation.

Discussion

We have identified the E3 Ub ligase Triad3A (29) as an important negative regulator of 2DL4 function. This is the first report, to our knowledge, describing the regulation of KIR by ubiquitylation. Our data demonstrate that Triad3A recruitment promotes the direct polyubiquitylation and degradation of 2DL4, and expression of the E3 ligase dramatically reduces total expression of the receptor in cell lysates. However, Triad3A expression did not influence 2DL4 surface expression, endocytosis, or early signaling events triggered through the receptor. Nonetheless, Triad3A expression significantly suppressed cytokine production and blunted sustained NF-κB signaling in response to 2DL4 engagement. Furthermore, expression of Triad3A suppressed 2DL4 recycling to the cell surface and promoted trafficking of internalized 2DL4 away from the early endosome, which was previously shown to be a site of intracellular 2DL4 accumulation and signaling (8, 13). Importantly, we also showed that function of another NK cell activating receptor, NKp44, was not impacted by expression of Triad3A in the same NK cells. Therefore, we conclude that Triad3A selectively controls intracellular 2DL4 function.

It is well established that polyubiquitylation of lysine residues can tag transmembrane, cytosolic, and nuclear proteins for sorting to multivesicular bodies and subsequent transport to proteasomal or lysosomal degradation (16, 35). Several shuttle factors, such as RAD23, Dsk2/Ub, and DDI1, contain both a Ub-binding domain and a proteasome-targeting motif, which bind to polyubiquitylated cargo proteins and direct their transport to the proteasome, respectively (36). Evidence is accumulating that attachment with different ubiquitylation branching arrays to proteins results in distinct functional outcomes: 1) polyubiquitylation chains linked at the Lys48 (K48) residue of the Ub molecules generally targets proteins to the proteasome for degradation; 2) K63-linked polyubiquitylation initiates intracellular signaling or trafficking; and 3) monoubiquitylation can alter protein activity, promote endocytosis, or target to lysosomal degradation (16). Our observation that polyubiquitylation of 2DL4 by Triad3A target only internalized receptors away from the early endosomes to a degradation pathway is consistent with K48-linked branching. Furthermore, a recent report demonstrated that Triad3A
can incorporate K48-linked polyubiquitin chains (31). Other examples of ubiquitylation-mediated trafficking of proteins away from early endosomes include the diubiquitylation of Ig-β of the B cell–Ag receptor complex by Itch (37) and the monoubiquitylation of Lst2 protein (38), although neither of these proteins are targeted to the proteasome.

FIGURE 7. Triad3A alters 2DL4 turnover and vesicle-mediated internalization is required for cytokine production. A, 2DL4 internalization was not affected in KHYG-1 cells cotransduced with Triad3A. KHYG-1 cells transduced with FLAG-2DL4 ± Triad3A were assayed for 2DL4 internalization as in Materials and Methods. Results are mean ± SD of eight experiments. B, 2DL4 turnover was suppressed in KHYG-1 cells cotransduced with Triad3A. KHYG-1 cells expressing FLAG-2DL4 ± Triad3A were assayed for 2DL4 turnover as in Materials and Methods. Results are mean ± SD from three experiments. C, DN dynamin blocks 2DL4-mediated IL-8 production in 293T cells. 293T cells were not transfected (NT) or transfected with FLAG-2DL4 ± DN-dynamin and tested 48 h later for IL-8 production by ELISA. D, Dynasore inhibits 2DL4-mediated IL-8 production in 293T cells. 293T cells were transfected with FLAG-2DL4 and cultured with indicated concentrations of dynasore for 48 h and tested for IL-8 secretion by ELISA. E, 2DL4-mediated IL-8 production in KHYG-1 cells was suppressed by dynasore. KHYG-1 cells pretreated with 40 μM dynasore for 30 min were stimulated with either plate-bound anti-FLAG mAb (M2) or anti-NKp44 (3.43.13) and tested 24 h later for IL-8 secretion by ELISA.

FIGURE 8. Intracellular trafficking of engaged 2DL4 to early endosomes is reduced by Triad3A. KHYG-1 cells transduced to express myc-2DL4 ± Triad3A were stained with anti-myc Ab + AlexaFluor 647-labeled secondary Ab on ice, cultured at 37°C for 2 h (A, B) or 1 h (C, D), settled onto poly-L-lysine–coated slides, fixed, permeabilized, and stained with polyclonal Ab to early endosomal markers (Rab5, A, B; or EEA1, C, D) plus secondary Ab conjugated with Alexa Fluor 350. Cells were imaged by bright field and immunofluorescence microscopy for myc (2DL4; red) and Rab5 or EEA1 (green). A, Bright field and overlaid max-projected fluorescence images of all z-stack sections from three representative cells stained for Rab5 from each condition (± Triad3A expression). B, Mean ± SE percentage area of 2DL4 compartmentalized with Rab5 was quantified using MetaVue software from max-projected images of z-stacks of 12–15 cells for each bar. C, Bright field and overlaid max-projected fluorescence images of all z-stack sections stained with EEA1 from three representative cells from each condition. D, Mean ± SE percentage area of 2DL4 compartmentalized with EEA1 was quantified using NIS-Elements software from all of the individual z-sections from 15 cells for each bar (>200 data points/bar). Percentage values were compared using the two-tailed Mann–Whitney U test, and resulting p values are listed in B and D. Original magnification ×60.
We previously reported that 2DL4-mediated cytokine production requires activation of MAPK and downstream activation of NF-κB (12). In this study, we have found that Triad3A overexpression in the NK cell line KHYG-1 does not affect 2DL4-mediated early activation profiles of ERK, JNK, p38, and IKK-α/β. We conclude that these 2DL4-mediated signaling events occur at the cell surface, and the surface expression and membrane-proximal function of 2DL4 were unchanged in Triad3A-expressing cells. The reduction of total 2DL4 protein levels by Triad3A was most likely due to ubiquitylation-mediated degradation of the intracellular pool of receptor, and we observed a coordinate reduction in sustained NF-κB activation, which we conclude to be critical for transducing intracellular signals leading to cytokine release. In this model, 2DL4 signals sequentially, first from the cell surface and subsequently from an intracellular endosomal compartment. Taken together, our data demonstrate that both early MAPK stimulation and sustained activation of NF-κB are necessary for the induction of 2DL4-mediated cytokine production, and Triad3A disrupts the latter signal.

The Triad3A-mediated reduction in sustained activation of NF-κB is consistent with growing evidence that the E3 ligase targets the NF-κB pathway, particularly in innate immune responses. Chuang et al. (29) reported that Triad3A interacts with distinct TLRs (TLR4, -5, and -9, but not TLR2) and downregulates their function. Importantly, the same report demonstrated that Triad3A inhibited the capacity of these TLRs to stimulate NF-κB reporters by promoting receptor ubiquitylation and degradation via the proteasome. Triad3A has also been shown to act as a negative regulator of TNF-α– and IL-1–mediated activation of NF-κB by associating with and promoting the degradation of the NF-κB signaling proteins RIP-1, TIRAP, and TRIF (30, 39). Recently, Triad3A was also shown to interact with and induce ubiquitylation and degradation of TRAF3 (31). Triad3A was further shown to negatively regulate RIG-I/MAVS-mediated NF-κB activation through targeting TRAF3, thereby modulating innate immune receptor responses toward several invading pathogens (31). In view of the impacts of Triad3A on the receptor-proximal NF-κB signaling pathway, we cannot rule out that direct recruitment of the E3 ligase to 2DL4 may similarly promote the ubiquitylation and degradation of receptor-associated signaling proteins within the NF-κB pathway. Our data, however, are to our knowledge the first to demonstrate that Triad3A specifically influences late-term NF-κB signaling at an intracellular site, but does not disrupt membrane proximal events.

Six different alternative spliced forms of Triad3 have been reported, named Triad3 and Triad3A–E (29), and all of these contain the C-terminal domain found to interact with 2DL4 in our yeast screen. The major protein form that we have identified in NK cells migrates nearly identical to that of Triad3A in SDS-PAGE. Although our studies have therefore focused on the impacts of the common Triad3A form, it is possible that other differentially spliced variants also influence 2DL4 function.

Our data indicate that 2DL4 ubiquitylation by Triad3A is occurring subsequent to internalization, and this prevents accumulation of the receptor in Rab5+/EEA1+ early endosomes to disrupt function. It has been shown that 2DL4 is internalized in a dynamin-dependent manner to early endosomes after receptor ligation in NK cells or 293T cells (8). Consistent with a recent report (13), we show that DN-dynamin and the dynamin inhibitor dynasore suppress 2DL4-induced production of IL-8 in both 293T cells and NK cells, indicating a major role for internalized receptor in cytokine production. Although it is believed that ligand-induced endocytosis is a mechanism of receptor inactivation, numerous studies have shown that receptors can remain active within the endosomal compartment (14, 15), and the temporal dynamics of receptor signaling can dramatically influence functional outcomes (40). Our results indicate that the cytokine-producing function of 2DL4 requires intracellular shuttling of the receptor to early endosomes to stimulate prolonged signaling, which is suppressed by Triad3A. In this way, polyubiquitylation of 2DL4 by Triad3A prevents surface recycling and shuts the receptor away from the early endosomes, thereby negatively regulating 2DL4 function by limiting the lifetime of its active signaling state at this intracellular site.

Acknowledgments

We thank Drs. Dietmar Kappes and Siddharth Balachandran for constructive advice on the manuscript, Dr. Suresh Basagoudanavar for technical assistance, Dr. Edna Cukierman for assistance in analyzing the immunofluorescence microscopy data, Dr. Xin-Ming Li for two-dimensional gel electrophoresis, and Drs. Erica Golemis, Roger Brent, Brent Passerin, and Ilya J. Serebriiskii for advice and reagents during the yeast two-hybrid screening. We also thank Drs. Marco Colonna, Garry Nolan, Lynn Heasley, Tung-Hsein Chuang, Keiji Tanaka, Shao Cong-Sun, Kiyonao Sada, and Masato Yagita for reagents, and special thanks also to the DNA Synthesis, DNA Sequencing, Flow Cytometry, Biochemistry and Biotechnology, and Cell Culture Facilities at Fox Chase Cancer Center.
