Suppression of Th2-Driven Airway Inflammation by Allergen Immunotherapy Is Independent of B Cell and Ig Responses in Mice

Soheila Shirinbak,* 1 Yousef A. Taher,† 1 Hadi Maazi,* Renée Gras,* Betty C. A. M. van Esch,† Paul A. J. Henricks,† Janneke N. Samsom,‡ J. Sjef Verbeek,§ Bart N. Lambrecht,¶ Antoon J. M. van Oosterhout,* 2 and Martijn C. Nawijn* 2

Allergen-specific immunotherapy (IT) uniquely renders long-term relief from allergic symptoms and is associated with elevated serum levels of allergen-specific IgG and IgA. The allergen-specific IgG response induced by IT treatment was shown to be critical for suppression of the immediate phase of the allergic response in mice, and this suppression was partially dependent on signaling through FcγRIIB. To investigate the relevance of the allergen-specific IgG responses for suppression of the Th2-driven late-phase allergic response, we performed IT in a mouse model of allergic asthma in the absence of FcγRIIB or FcγRI/FcγRIII signaling. We found that suppression of Th2 cell activity, allergic inflammation, and allergen-specific IgE responses is independent of FcγRIIB and FcγRI/FcγRIII signaling. Moreover, we show that the IT-induced allergen-specific systemic IgG or IgA responses and B cell function are dispensable for suppression of the late-phase allergic response by IT treatment. Finally, we found that the secretory mucosal IgA response also is not required for suppression of the Th2-driven allergic inflammation by IT. These data are in contrast to the suppression of the immediate phase of the allergic response, which is critically dependent on the induced allergen-specific serum IgG response. Hence, IT-induced suppression of the immediate and late phases of the allergic response is governed by divergent and independent mechanisms. Our data show that the IT-induced suppression of the Th2 cell-dependent late-phase allergic response is independent of the allergen-specific IgG and IgA responses that are associated with IT treatment. The Journal of Immunology, 2010, 185: 000–000.

A llergen exposure in sensitized individuals results in cross-linking of IgE bound to FceRI on the mast cell surface and induces the immediate type I hypersensitivity response, which is driven by inflammatory mediators released from the mast cells (1). This immediate-phase allergic response is strictly IgE dependent and is treated by pharmacotherapy aimed at blocking mast cell effector molecules, such as histamine. The late response to allergen exposure in sensitized individuals results in cross-linking of IgE bound to FceRI on the mast cell surface and induces the immediate type I hypersensitivity response, which is driven by inflammatory mediators released from the mast cells (1). This immediate-phase allergic response is strictly IgE dependent and is treated by pharmacotherapy aimed at blocking mast cell effector molecules, such as histamine. The late response to allergen exposure is characterized by an influx of eosinophils, neutrophils, basophils, and activated CD4 T cells and is sensitive to immunosuppressive drugs, such as steroids (1). Allergen-specific immunotherapy (IT) is the only disease-modifying treatment for allergic disorders and consists of a series of s.c. injections with increasing doses of allergen, which induces long-term desensitization and relief of symptoms (2, 3). It is commonly used for the treatment of allergic rhinitis and insect venom hypersensitivity, yet its efficacy in allergic asthma is controversial. The main drawbacks of IT are the long-term treatment protocols and the risk for eliciting anaphylactic reactions (2). Improvement of safety and efficacy can only be achieved by characterizing the immunological mechanisms that contribute to IT-induced suppression of allergic inflammation in more detail.

Although the critical mechanisms by which IT suppresses allergic symptoms have not been fully identified, several potential mechanisms have been postulated to contribute to IT, converging on the modulation of Tand B cell responses to the allergen (4). With regard to the T cell responses, IT was postulated to divert the allergen-specific Th2 response into Th1 responses and induce regulatory T cell activity (5). With regard to the B cell responses, IT was shown to induce an IgG1 and IgG4-dominated Ab response to the allergen with a mild increase in IgA levels, whereas the serum levels of allergen-specific IgE showed an early increase followed by a long-term gradual decline (1). However, the relationship between the efficacy of IT and induction of allergen-specific IgG remains controversial, with serum concentrations of allergen-specific IgG not consistently correlating with clinical improvement (1, 6, 7).

The increase in IgG serum levels, and especially IgG4, following IT treatment led to the formulation of the blocking Ab hypothesis, which states that the IgG Abs compete with IgE for binding to the

The increase in IgG serum levels, and especially IgG4, following IT treatment led to the formulation of the blocking Ab hypothesis, which states that the IgG Abs compete with IgE for binding to the
Sensitization, challenge, and IT protocol

The short-term protocol (OVA-IT in OVA-sensitized mice, Fig. 1D) was the same as previously described (19). Briefly, mice received two i.p. injections of 10 μg OVA (endotoxin-free, <0.5 U/ml; Seikagaku Kogyo, Tokyo, Japan) adsorbed onto 2.25 mg alum (Inmet/Alum, Pierce, Rockford, IL) in 100 μl methylcellulose (pH 6.5). Methylcellulose was removed by centrifugation (10,000 g for 10 min) twice. Two weeks after the second sensitization, mice were treated with three s.c. injections of 1 mg OVA in 200 μl pyrogen-free saline (IT) or 200 μl saline (sham) on alternate days. One week after the last OVA or sham treatment, mice were challenged three times every third day with OVA aerosols in saline (1% w/v) for 20 min in a Plexiglas exposure chamber coupled to a Pari LC Star nebulizer (PARI Respiratory Equipment, Richmond, VA; particle size 2.5–3.1 μm). Mice were killed by cervical dislocation 1 wk after the last challenge. The effects of possible endotoxin contamination in the OVA preparations on the efficiency of IT was previously tested in our laboratory (A.J.M. van Oosterhout and B.C.A.M. van Esch, unpublished data), and all OVA preparations used in these experiments were in the lower range of endotoxin levels that were shown to efficiently induce IT-dependent suppression of allergic inflammation (0.5–500 endotoxin unit/ml).

Airway responsiveness to methacholine, serum levels of Igs, cellular infiltration, and Th2 cytokine levels in bronchoalveolar lavage (BAL) fluid were measured 24 h after the last OVA inhalation challenge in each mouse.

Measurement of airway responsiveness

Airway responsiveness was assessed by measuring airway resistance in response to i.v. administration of increasing doses of methacholine (acetyl-b-methylcholine chloride, Sigma-Aldrich, St. Louis, MO) as described previously (24). Briefly, anesthetized (ketamine/domitor) mice were attached to a computer-controlled small-animal ventilator (Flexivent; SCIREQ, Montreal, Quebec, Canada). Mice were ventilated at a breathing frequency of 280 breaths/min and a tidal volume of 10 μl/kg, which was pressure limited at 800 mm H2O. Airway resistance in response to increasing doses of methacholine was calculated from the pressure response to a 2-s pseudorandom pressure pulse, as described previously (24).

Determination of serum levels of OVA-specific Igs

Blood for assessment of serum IgS was collected 7 d before the first OVA aerosol challenge (via orbital puncture) and 24 h after the last challenge (via cardiac puncture). Serum was collected, and OVA-specific IgE, IgG1, IgG2a, and IgA levels in serum were measured by ELISA, as described previously (18). A reference standard was used with arbitrary units of each isotype of 1000 experimental unit/ml. The detection levels of the ELISAs were 0.05 experimental unit/ml for IgG2a, 0.5 experimental unit/ml for IgE and IgA, and 0.005 experimental unit/ml for IgG1.

Analysis of the cellular composition in BAL fluid

Immediately after bleeding, the lungs were lavaged through a tracheal cannula with 1 ml saline at 37°C containing 5% BSA and 2 mg/ml apomorphine (F. Hoffman-La Roche, Basel, Switzerland). Cells were pelleted, and supernatants were used for measurement of cytokines by ELISA. Subsequently, lungs were lavaged with 4 ml saline, and BAL cells were pooled and counted. For differential BAL cell counts, cytospin preparations were stained with Diff-Quick (Merz & Dade, Dudingen, Switzerland). Cells were differentiated into mononuclear cells, lymphocytes, neutrophils, and eosinophils by standard morphology. At least 200 cells were counted per cytospin preparation.

Measurement of cytokines

IL-5 and IL-13 in the BAL fluid were determined by ELISA, according to the manufacturer’s instructions (BD Pharmingen, San Diego, CA). The lower detection limits of the ELISAs were 32 pg/ml for IL-5 and 15 pg/ml for IL-13.

Statistical analysis

All data are expressed as mean ± SEM. The Mann–Whitney U test was used to analyze the results, and p < 0.05 was considered significant.

Results

OVA-specific IT suppresses airway inflammation and hyperresponsiveness in asthmatic mice

We previously developed and used a mouse model for OVA-specific IT in the classical OVA/alum mouse asthma model (18). In this

Materials and Methods

Animals

Animal housing and experiments were performed in accordance with the guidelines of the Institutional Animal Care and Use Committee at the University of Groningen. All mice used in the experiment were 6–8 wk-old males. Mice deficient for FcγRIII and FcγRIIB and polymeric IgR (pIgR)-deficient mice were on the BALB/c background. Wild-type BALB/c control mice were obtained from Charles River Laboratories (Maastricht, The Netherlands). B cell-deficient Igλ3g(–/–) (μMT) and wild-type littermates (both on a C57BL/6 background) were purchased from The Jackson Laboratory (Bar Harbor, ME). All mice were housed in Makrolon cages in a laminar flow cabinet and provided with food and water ad libitum.
model, gradual up-dosing or application of three high doses of OVA by s.c. injections in OVA/alum-sensitized mice renders these mice protected against clinically relevant asthma manifestations, such as eosinophilic airway inflammation and AHR upon subsequent OVA inhalation challenge. In this model, the mice have not experienced an asthmatic response prior to the IT treatment, which is in contrast to the routine clinical situation in which a patient is treated with allergen-specific IT only upon presenting with clinical manifestations of an atopic disease, such as rhinitis or allergic asthma. Hence, we first tested whether OVA-specific IT would also be protective in mice that had experienced a prior OVA-induced asthmatic response. To address this question, we designed the experimental layout depicted in Fig. 1A. Before IT treatment, mice were given an OVA/alum sensitization followed by OVA inhalation challenges (asthmatic mice) or PBS control treatment (sensitized-only mice). Two weeks after the last OVA/PBS inhalation challenge, both groups (sensitized only and asthmatic) were sham (saline) or IT (OVA) treated. After an additional 2 wk, all groups received a series of three OVA inhalation challenges to induce the asthma phenotype, and AHR to methacholine was assessed by direct measurement of airway resistance, followed by section as described in Materials and Methods.

As shown in Fig. 1B, OVA-inhalation challenges in sham-treated mice that had not received prior OVA-inhalation challenges (sensitized only) induced a dose-dependent increase in AHR to methacholine, which was increased compared with PBS-challenged control mice. In concordance with the data from our previous studies, OVA-inhalation challenges in OVA-IT–treated sensitized-only mice induced a significant reduction in airway responsiveness, almost to the level of PBS-challenged control mice (Fig. 1B). These data are in agreement with our previous studies (18, 24) in which we showed that OVA-specific IT efficiently repressed the induction of an asthmatic phenotype by OVA-inhalation challenges in OVA/alum-sensitized mice.

Importantly, OVA challenges in sham-treated mice that had received prior OVA-inhalation challenges (asthmatic mice) induced a similar level of AHR compared with sham-treated sensitized-only mice, indicating that the AHR to methacholine was similar between the first and second series of OVA-inhalation challenges. Remarkably, OVA-IT also strongly suppressed the AHR to methacholine in the asthmatic mice (Fig. 1B), supporting the notion that OVA-IT in our mouse model suppresses AHR, irrespective of the presence of a pre-existing asthmatic phenotype in the treatment group.

Analysis of the eosinophilic airway inflammation yielded similar results (Fig. 1C). OVA-IT treatment in sensitized-only mice reduced the BAL numbers of eosinophils compared with sham treatment, as we reported in several previous studies (18, 19, 24–26), although the effect was not statistically significantly ($p = 0.161$) in this specific experiment. Importantly, however, OVA-IT in asthmatic mice strongly and significantly suppressed the levels of BAL eosinophils (Fig. 1C), indicating that OVA-IT also renders protection against the induction of eosinophilic airway inflammation in mice that received prior OVA-inhalation challenges. Taken together, these data indicate that OVA-IT in the mouse model of OVA-induced asthma efficiently suppresses the induction of clinically relevant asthma phenotypes upon OVA-inhalation challenges, irrespective of the presence or absence of a prior asthma phenotype at the time of OVA-IT treatment. Therefore, the remaining experiments were performed using the short protocol as our model for IT, using sensitized-only mice as the recipient for the IT injections (Fig. 1D).

**OVA-specific IT suppresses the late-phase allergic response in FcγRIIB-deficient mice**

IT treatment in human subjects, as well as in mouse models, induces strong allergen-specific IgG responses (1, 18), which were shown to be critically required for suppression of the immediate response in a mouse model of Fel d1 IT (20). We hypothesized that induction of an allergen-specific IgG response by IT is critical for suppression of the Th2-dependent late-phase allergic response in an FcγRIIB-dependent fashion. To test our hypothesis, we assessed whether IT treatment was able to suppress Th2 cell-mediated allergic inflammation in the absence of FcγRIIB signaling. To this end, we performed our
OVA-sensitized and sham-treated wild-type or FcγRIIB−/− mice, OVA aerosol challenges induced a significant OVA-specific IgE response (Fig. 2A, pre- versus postchallenge). In addition, the OVA challenges induced moderate IgG1, IgG2a, and IgA responses in sensitized and sham-treated wild-type and FcγRIIB−/− mice (Fig. 2B–D). OVA-IT treatment in sensitized wild-type mice induced a strong IgG1 and IgG2a response, which was not further upregulated by subsequent OVA challenges as we showed previously (18). In FcγRIIB−/− mice, OVA-IT also induced strong IgG1 and IgG2a responses (Fig. 2B, 2C), in agreement with the recent observations in the mouse model of Fel d 1 IT (20). Finally, OVA-IT strongly suppressed the OVA-specific IgE response in wild-type mice (Fig. 2A). Surprisingly, FcγRIIB−/− mice also displayed a strong reduction in the OVA-specific IgE response upon OVA-IT, indicating that the IT treatment efficiently suppressed allergen-specific IgE, independent of FcγRIIB signaling. Remarkably, the OVA-specific IgA response induced in wild-type mice by OVA-IT was not observed in FcγRIIB mutant mice (Fig. 2D).

Because OVA-IT efficiently suppressed the allergen-specific IgE response in mice deficient for FcγRIIB, we next analyzed Th2-driven eosinophilic airway inflammation. In line with the observed loss of the OVA-specific IgE response after OVA-IT treatment, wild-type mice displayed an aborted eosinophilic airway inflammation upon OVA-IT, accompanied by strongly decreased local Th2 cell activity, as measured by IL-5 and IL-13 levels in BAL fluid (Fig. 3). Intriguingly, FcγRIIB mutant mice showed an identical suppression of eosinophil cell counts, as well as IL-5 and IL-13 levels, in BAL fluid after OVA-IT. Taken together, these data indicate that OVA-specific IT is fully capable of suppressing allergen-specific IgE responses, as well as Th2-driven eosinophilic airway inflammation, in the absence of FcγRIIB-dependent signaling.

**OVA-specific IT suppresses IgE responses and Th2-driven inflammation in FcγRI/FcγRIIIB−/− mice**

Although the suppressive activities of FcγRIIB signaling on mast cell activation and APC function are well established (10), cross-linking of FcγR by OVA–IgG immune complexes was also shown to induce IL-10 expression in macrophages through FcγRI (14), resulting in deviation of the T cell phenotype and induction of an OVA-specific IgG response (13). Hence, we next aimed to assess whether signaling of IgG–allergen immune complexes through FcγRI or FcγRIII contributed to the IT-induced IgG and IgA responses or the suppression of the late-phase allergic response. To this end, we performed OVA-IT in double-mutant FcγRI−/−/FcγRIIIB−/− mice. As observed in wild-type mice, the OVA-specific IgE response was strongly suppressed by OVA-IT treatment in FcγRI/FcγRIIIB−/− mice and was accompanied by strongly increased OVA-specific IgG1 and IgG2a responses (Fig. 2A–C). These data indicate that neither the increased IgG responses induced by IT nor the suppression of IgE responses are dependent on FcγRI or FcγRIIIB signaling. Interestingly, we found that although OVA-IT induced significantly increased OVA-specific IgA levels in wild-type mice, decreased levels of OVA-specific IgA were detected in serum from FcγRI/FcγRIIIB−/− mice after OVA-IT.

To evaluate the suppression of allergic airway inflammation by OVA-IT in FcγRI/FcγRIIIB−/− mice, we also analyzed eosinophil counts and Th2 cytokine levels in BAL after sham or OVA-IT treatment followed by OVA challenge. Similar to wild-type mice, BAL...
eosinophil counts in FcγRI/FcγRIII−/− mice were significantly decreased after OVA-IT compared with sham-treated mice (Fig. 3A). In addition, OVA-IT significantly reduced levels of IL-5 and IL-13 in BAL fluid compared with those of sham-treated FcγRI/FcγRIII−/− mice (Fig. 3B, 3C). Taken together, these data indicate that FcγRI/FcγRII-mediated signaling is not required for the suppression of the late-phase allergic response by IT. Hence, we next asked whether the allergen-specific Ig responses were required for the suppression of the Th2-driven allergic inflammation by allergen IT.

IT suppresses allergic airway inflammation in B cell-deficient mice

Because we showed that IT efficiently suppresses Th2 cell activity and eosinophilic airway inflammation in mice deficient for FcγRI and FcγRIII, as well as in mice deficient for FcγRIIB, FcγR-mediated signaling seems to be redundant for the suppression of the late-phase allergic response by IT. Nevertheless, IT treatment induces a strong OVA-specific IgG response in FcγRIIB−/− mice and FcγRI−/−/FcγRIII−/− mice (Fig. 2B, 2C). Therefore, we aimed to test whether the IgG serum responses contribute to IT by a non-FcγR-dependent mechanism. Moreover, we wanted to assess the putative role of IL-10–producing B cells (27) in the IT-dependent suppression of Th2 cell activity. Therefore, we subjected B cell-deficient μMT mice to our mouse model of IT in allergic asthma (Fig. 1D).

As a result of the functional inactivation of the H chain of IgM in μMT mice, B cell differentiation is arrested at the pro-B cell stage, and these mice lack most mature B cells capable of producing Ig (28). Except for some residual mucosal IgA production (29), IgM and IgG serum responses are absent in μMT mice. Interestingly, in...
the OVA/alum mouse model of allergic asthma, μMT mice were shown to display Th2 cytokine production and airway eosinophilia and hyperresponsiveness, despite the absence of OVA-specific IgE responses (30). Therefore, the μMT mouse model allows analysis of the regulation of the allergen-specific Th2 cell-driven late-phase allergic response by IT in the absence of allergen-specific IgE and IgG and systemic IgA responses and the immediate phase of the allergic response.

To confirm that our IT protocol was successful, we first evaluated serum levels of OVA-specific IgE in wild-type controls. As expected, OVA-IT significantly inhibited the OVA-specific IgE response induced by OVA inhalation in sham-treated mice (Fig. 4A). Furthermore, the IT treatment itself induced a strong upregulation of OVA-specific IgG1 levels, in agreement with our typical IT-induced Ig responses.

To evaluate the suppression of Th2-driven airway inflammation after OVA-IT in μMT mice, we measured eosinophil cell counts and Th2 cytokine levels in BAL fluid. After sham treatment, OVA challenge resulted in high IL-5 levels in BAL fluid and the infiltration of a high number of eosinophils into the airways in wild-type and μMT mice (Fig. 4B, 4C). As expected, BAL levels of IL-5 and airway eosinophilia were strongly suppressed by OVA-IT in wild-type mice. Interestingly, the same level of suppression of BAL IL-5 and airway eosinophilia was observed in IT-treated μMT mice (Fig. 4B, 4C), indicating that the suppression of Th2 cell activity and allergic inflammation by allergen-specific IT is exerted independently of the allergen-specific IgG and systemic IgA responses induced by IT.

**Suppression of allergic inflammation by IT in plgR-deficient mice**

Our data in the μMT mouse model indicate that the IgG and systemic IgA responses induced by OVA-IT are dispensable for the suppression of Th2-driven allergic inflammation. Nevertheless, μMT mice were shown to retain a functional mucosal B cell population that is capable of producing luminal IgA (29). Because airway delivery of allergen-specific IgA to sensitized mice was shown to suppress airway responses upon subsequent allergen challenge and to induce a systemic allergen-specific IgG2a response (31) resembling some IT-induced phenotypes, we wanted to test whether modulation of the airway luminal IgA response by IT could contribute to the suppression of allergic inflammation. To this end, we performed our mouse model of OVA-IT in plgR-deficient mice, which are incapable of transporting polymeric IgA across the airway epithelium and, therefore, lack luminal IgA (32). As shown in Fig. 5, plgR-deficient mice displayed a strong IgG1 response upon OVA-IT treatment (Fig. 5B). In contrast, the OVA-specific IgG2a response induced by OVA-IT in wild-type mice was not observed in plgR−/− mice, even though...
these mice have a higher basal level of OVA-specific IgG2a after sensitization (Fig. 5C). Nevertheless, OVA-specific IgE responses are suppressed by OVA-IT in pIgR−/− and wild-type mice to a similar degree (Fig. 5A). Finally, the OVA-specific serum IgA responses were strongly increased in pIgR−/− mice, in agreement with previous observations (32, 33), but no differential effect of IT treatment on serum IgA was seen between wild-type and pIgR−/− mice (Fig. 5D). Surprisingly, measurement of OVA-specific IgA levels in BAL of the nontransgenic littermates indicated that, in our model, OVA inhalations in IT-treated mice resulted in a reduced level of BAL IgA compared with OVA inhalations in sham-treated control mice, although the differences were not statistically significant (1504.5 ± 673.49 experimental unit/ml in IT versus 5978 ± 1545.4 experimental unit/ml in sham-treated controls; \( p = 0.157 \)).

To extend our findings to the effects of IT on the suppression of Th2-driven airway inflammation in pIgR−/− mice, we also analyzed BAL Th2 cytokine levels and eosinophil cell counts (Fig. 6). IL-5 levels and eosinophil cell counts in BAL were equally suppressed by OVA-IT in wild-type and pIgR−/− mice, indicating that the suppression of allergic inflammation by IT is independent of airway luminal IgA levels.

**Discussion**

We present a comprehensive set of data assessing the relevance of allergen IT–induced Ig responses for the suppression of the Th2-driven allergic inflammation that underlies the late-phase allergen IT–induced Ig responses for the suppression of the Th2-driven airway inflammation in the OVA-driven mouse model of allergic response. We show evidence that cardinal features of the late-phase allergic response are strongly increased in pIgR−/− mice, in agreement with previous observations (32, 33), but no differential effect of IT treatment on serum IgA was seen between wild-type and pIgR−/− mice (Fig. 1C; compare sham-treated asthmatic mice with sham-treated sensitized-only mice), which might be attributed to the repeated OVA inhalations in this extended IT protocol. This observation underscores the notion that the data from these mouse studies can only be extrapolated to the human situation with great care. Nevertheless, the suppressive effect of repeated airway administrations with OVA was not observed on the AHR to methacholine, and, importantly, OVA-IT still suppressed AHR and airway eosinophilia in the asthmatic group very efficiently, indicating that despite the side effects of repeated OVA exposure, IT is still fully operational. Importantly, the three high doses of OVA used in our model were previously shown to be as efficacious as a gradual up-dosing of OVA in the mouse model (18), and suppression of clinically relevant parameters of the asthmatic phenotype, such as AHR and airway eosinophilia, are as efficiently suppressed by the IT treatment in mice that were only sensitized to OVA as in mice that had experienced a prior asthmatic phenotype at the time of IT treatment, the latter reflecting the clinical practice more closely.

In human allergic individuals, allergen IT was shown to efficiently suppress the late phase of the allergic response (37–39), associated with reduced numbers of infiltrating T cells, basophils, neutrophils, and eosinophils. Intriguingly, the effects of IT on the immediate phase of the allergic response are modest, although a reduction in the magnitude of the immediate-phase allergic response was reported (39, 40). The most prominent response to allergen IT treatment in allergic individuals is the induction of allergen-specific IgG1 and IgG4 responses, yet the relevance of the IT-induced IgG Ab response has remained controversial (1). Although some studies reported observations that indicate a contribution of blocking Abs to IT (41), several groups failed to show a correlation between the presence of neutralizing IgG Abs and improved clinical outcome (6, 42). The allergen-specific IgG Abs might contribute to IT by blocking access of the allergen to IgE on mast cells or basophils or by preventing FceRI-dependent mast cell activation by binding to FcyRIIB (reviewed in Ref. 1). Upon cross-linking of the FcεRI-IgE complex on the mast cell surface with the FcyRIIB–IgG complex by the same multivalent ligand, FcyRIIB ITIM phosphorylation by FcεRI-associated kinases can directly suppress FcεRI signaling and mast cell activation (43, 44). In the mouse model of Fel d1–specific IT, both mechanisms have been postulated to contribute to the suppression of the immediate phase of the allergic response (20). Although suppression of systemic anaphylaxis by IT was critically dependent on FcyRIIB signaling, suppression of tissue mast cell degranulation was maintained in FcyRIIB-deficient mice. Remarkably, the suppression of the systemic and the local immediate-phase allergic response could be passively transferred by serum or the serum IgG fraction, indicating the requirement for allergen-specific IgG (20). The allergen-induced Th2 cell-driven airway inflammation (21, 22) and AHR (23)
in the OVA/alum mouse model of experimental allergic asthma were previously shown to be independent of allergen-specific IgE responses and the immediate-phase allergic response induced by cross-linking of IgE on mast cells and basophils. This is in marked contrast to the human situation, in which allergic asthma is characterized by a clear immediate and late-phase allergic response, depending on allergen-specific IgE and Th2 cells, respectively (45). Our mouse model of OVA-IT exclusively allows the analysis of the mechanism by which the treatment suppresses the late-phase allergic response. We found that the allergen-specific IgG response induced by IT is not critically required for suppression of the Th2 cell-dependent late-phase allergic response or the allergen-specific IgE responses.

The FcγRIIB-independent suppression of allergen-specific IgE responses was also observed in the Fdl d1 virus-like particle vaccination study (20). Although the investigators hypothesized a contribution of the ssRNA within the virus-like particles to suppression of the IgE response through TLR3/7 signaling, our data replicate their findings on the FcγRIIB-independent suppression of the IgE response by IT, even in the absence of TLR signaling. Therefore, the mechanism by which allergen IT represses the IgE response seems to be independent of direct suppression of IgE-producing B cells via FcγRIIB (46, 47). In fact, the IT-induced suppression of the Th2-driven allergic inflammation and the allergen-specific IgE responses seem to correlate, indicating that inhibition of Th2 cell activity might be critical for the reduced IgE levels after IT.

In serum, OVA-IT induces a specific IgA response in our mouse model (Fig. 2D), in agreement with human studies (15, 16). Nevertheless, the use of a reference serum containing an arbitrary level of OVA-specific IgA as a standard in these assays precludes the absolute quantification of the OVA-specific IgE levels induced by OVA-IT or a direct comparison with the magnitude of the OVA-specific IgG response. Consequently, the biological relevance of this response remains to be determined. Moreover, the secreted OVA-specific IgG response. Consequently, the biological relevance of this response remains to be determined. Moreover, the secreted OVA-specific IgG response induced by IT is not critically required for suppression of the late-phase allergic response or the allergen-specific IgE responses.

In summary, to our knowledge, we demonstrate for the first time that the allergen-specific IgG and IgA responses induced by allergen-specific IT in a sensitized host are not critically required for the suppression of allergen-specific IgE responses and the Th2 cell-driven late-phase allergic response upon allergen provocation. This is in marked contrast to recent data showing that allergic desensitization by an Fel d1 vaccination strategy caused suppression of the immediate phase of the allergic response that could be passively transferred by serum or the serum IgG fraction and which was, in part, dependent on FcγRIIB signaling (20). We postulate that allergen-specific IT suppresses the immediate and late-phase allergic response by divergent and independent mechanisms. Other mechanisms that could contribute to the IT-induced suppression of allergic inflammation, such as local IL-10 production, induction of regulatory T cells, or immune deviation to Th1 or Tr-1 cells, need to be addressed in future studies.
